No. 1

## On Permanently Locating Agricultural Exhibitions.

Under the head of "the management of Agricultural Societies," the last number of our talented contemporary, *the Country Gentleman*, has some very useful and practical remarks that deserve the best attention of all who are interested in the prosperity of these institutions. It would appear that farmers the other side of the lines, as well as on this, do not take that deep interest in the business of agricultural societies which they ought, but complain at home that the management is inefficient, whereas if they had done their duty by attending the annual meetings and taking their proper share of the work and responsibility, the defects and shortcomings which they so loudly complain of might have been, in great measure, prevented.

It appears that the question of permanent location has for some time engaged the attention of the friends and directors of Agricultural Societies in several of the States of the American Union, but that no general or very decided conclusion has as yet been reached. The question is evidently a complex one, and requires to be viewed and discussed on both sides; and our cotemporary offers a number of useful and common-sense suggestions that must be acceptable to such as desire to form correct notions on the subject. We are decidedly of opinion that no rule can be arrived at in an extensive Province like Canada, or,

perhaps, in any one of the States, that will admit of general, or, at least, unmodified application, as so much must depend on location, and sectional views and feelings. The union of township and even county societies occasionally for exhibition purposes, as permitted by our statute, when mutually desired, would doubtless prove beneficial. To enlarge the sphere of combination rather than diminish it is, no doubt, the true policy to be pursued. The chief value of Township Societies is the collecting of the best articles furnished by the locality, and creating therein a feeling of emulation, *with reference to the County and Provincial Exhibitions*. Our theory in Canada is that township, county, and Provincial societies, form mutual links of one great chain of agricultural operations; and the success of each, as well as of the whole, materially depends upon the manner in which this spirit of mutual dependance is practically carried out. The good and efficient working of *the whole* is the great object to be sought. Our cotemporary asks,

*"Is there not some method by which the advantages of both the permanent and migratory systems can be combined, by a Society occupying a still wider field of labor?"*

"The Provincial Agricultural Society of Canada West appear to have successfully accomplished this. Kingston, Hamilton, Toronto and London, the four chief cities of the Province, having publicly appropriated or privately subscribed the amounts requisite for the purchase and laying out of grounds and the erection of substantial buildings, each en-

joys in turn the quadrennial visit of the Society. Its exhibitions do not become "an old story" in any one of them; nor are the grounds and buildings in disuse during the intervals between the Provincial Shows. On the contrary, the former are made to furnish a fine park for constant and general resort, and the main building is of such nature as to be of service for public gatherings of any extraordinary size, while the buildings and grounds are also occupied by the County Society for its usual autumn shows.

\* \* \* \* \*

"We have for many years been convinced—we were so, before the experiment had been thought of by our Canadian brethren—that we shall ultimately be led to the adoption of such a system. We have watched public opinion gradually coming around, unless we much mistake, to a similar position. At least the discussion of the subject can do no harm. If it is objected that these are not "the times" to secure contributions for such a purpose, we reply that *all the outlay need not be made at once*; only let the city which secures the holding of the next Fair, in the assurance that in three, four or five years, it will again be selected, expend what it does expend in a permanent way, and so as to unite the objects of its local Societies, Agricultural and Horticultural, if there are both, with those of the State Society—and we shall have a beginning, to which additions can be annually made, until by the time the turn of the same place next comes, all the demands of the Society and the public would probably be fully met.

"But if our Cities are to take up the question as one of exactions from some greedy corporation, we shall have no hope of early success. So have not done the Canadian towns just mentioned. With them it has been matter of public pride and generous rivalry, to outvie one another in the character of the accommodation furnished,—well knowing that the better the public are suited, the more largely they will be present on such occasions. And when four years shall have run their round, each city expects a golden verdict upon the efforts it has put forth. They have moreover had in view the healthful recreation constantly afforded to their own citizens by the possession of such grounds, the conveniences of the buildings for public uses, and their presence as ornaments and objects of attraction to the city. Whether they have thought once for the farmers and twice for themselves, or twice for the farmers and once for themselves, we do not know: but they have had wisdom and intelligence enough to discern that the interests of both City and County are common, and constantly blending, and that nothing can be done which promotes the prosperity and intelligence of the one, without reacting in a similar way for the benefit of the other."

So far as our *Provincial Exhibitions* are concerned, the providing of permanent accommodation in four or five principal cities, as has been already done, in which they are held *alternately*, public opinion is most decidedly in favor of the new system; the full benefit of which, particularly in a pecuniary point of view, has not yet been attained. The first outlay in the erection of permanent buildings is necessarily heavy, and more or less difficult to meet, but when the next time comes for holding the show in the same place, a comparatively small expense only has to be incurred, and the great convenience and economy of the system will be equally and fully understood.

### Dairy Management.

Last year, that is 1861, a Peebleshire dairymaid published a little valuable tract, founded on her own observation and experience, on the important question of Dairy Management. It is to some of the more prominent points contained in this pamphlet that we invite the reader's attention.

Mrs. Agnes Scott, of Winkston, for that is the writer's name and address, begins at the beginning, when she tells us, "experience soon taught me that most milk and butter were produced when the *feeding* was most carefully attended to. In order to ensure this I superintended this department myself." At six o'clock, her cows are rubbed and littered down, and 4 or 5 lbs of straw per cow was given to them carefully, *quite dry*; at 8 o'clock the cows are milked; at 10 o'clock, they are fed with turnips, (a barrowful, or about 80 or 90 lbs., between three cows); or, failing this, a quart of peas or bean meal, mixed with a pint of water; at 10 o'clock, in *fine weather*, they are let out for an hour or two to water and exercise themselves, and in their absence the byres are thoroughly cleansed and aired; in bad weather they are kept in, and then a handful of oatmeal in three pints of luke-warm water is given to each cow three times a day, and in the first three pints a handful of common salt is dissolved. When the cows return to the byre, each one has 4 or 5 lbs. of straw, and between 4 and 5 o'clock, the same amount of turnips as in the morning; about 8 o'clock, 4 or 5 lbs. of meadow hay are given, and, in addition,

each recently calved cow has half a pailful of boiled turnips, mixed with a quart of peas or bean-meal rather more than lukewarm.—For four or five days after calving, Mrs. Scott does not give raw turnips. She says, “It is a great mistake to keep fodder in quantities lying unused; rather let the appetite be tested, and by keeping it always sharp, not only will the meal be eaten up with relish, but a much more healthy state will be maintained. The time of feeding should be regulated according to the season; milking time should also be so fixed that it may be *regularly kept*, and kept so as to be suitable not only for the parties engaged in it, but so as not unduly to disturb either the rest or feeding of the cows.”

It is evident, then, that in Dairy practice, ceaseless attention is the great secret of success, and that there is something more in the business than can be learned from books. Dairy knowledge is generally traditional, and often hereditary. We never saw a slovenly dairymaid whose mother was noted for superior dairy management. Regular and discriminate feeding, warmth and perfect cleanliness, with proper ventilation, are the leading conditions of success; the neglect of any one of them will be sure to produce injury and loss. The proper management of milk in the dairy, and the conversion of it into cream, butter or cheese, are interesting and very delicate processes, equally demanding a system of order and perfect cleanliness, guided by experience and a discriminating judgment.

### Death of the Prince Consort.

It is our most painful duty to record the decease of a no less illustrious personage than the husband of our beloved Queen! This sad news has produced the intensest sorrow throughout the United Kingdom, and those British dependencies which it has already reached; and in a few weeks more the whole British Empire, on which it has been truly said that “the sun never sets,” will grieve as one family for the loss of so great and good a man. Her Majesty in bowing with trustful resignation to the Sovereign will of Heaven, under this most afflictive bereavement, will have the consolation of knowing that she has the deepest sympathies of her subjects, scattered over the greater portion of the earth.

As the late Prince Consort was as distinguished in the pursuits of agriculture as in those of science and art, and indeed in every thing which tends to refine and elevate the character of a people, we think that an agricultural journal, in perhaps, the most important agricultural colony under the crown of England, should not allow this solemn and mysterious dispensation of Divine Providence to pass, unnoticed; and we therefore cordially transfer to our pages the following article from the *Mark Lane Express*, of December 16th:—

“It was only at the General Meeting of the Royal Agricultural Society on Wednesday last, that the members came to hear of the illness which would prevent their august President from being amongst them. It is true that the indisposition of his Royal Highness had already been rumoured, and that he had not occupied his place at the Council Board of the week previous. But who could have ever foreshadowed the fatal result? And indeed the blow has fallen so suddenly, that it is difficult even now to thoroughly realize the calamity. Scarcely a month since it is when, in all the pride of health and mature manhood, in the full exercise of his high abilities and business habits, we had to congratulate the agricultural world on the active interest that the Consort of our Queen was showing in our cause. Under his gracious countenance, as with the many other Arts he had fostered, that of the husbandman promised still further to prosper, as certainly at no era in its history had the National Society given so much promise as when the Prince Consort took its fortunes into his keeping. And then, in a moment, our joy is turned into grief, and our holiday-week closes in mourning and lamentation.

This, however, is perhaps but the echo of a somewhat selfish feeling. For the loss of Prince Albert, as he was more familiarly called to the last, is a common loss to the country. It is not alone Agriculture that will look around aghast for a Patron, a Friend, and an Example. Refined in his tastes, exemplary in his domestic life, and with the highly cultivated manners of a gentleman and a scholar, the Prince proved himself in every way worthy to be the consort of so illustrious a Sovereign. And such, perhaps, will be his great praise; as, in fact, it could scarcely be greater. Debarred from any direct share in the actual business of the State, no man has ever lived a more blameless life as a husband, or maintained his high estate as the father of our future Kings with more dignity and respect. It would but ill become us here to intrude upon the sacred privacy of a bereaved family's sorrow, but we must repeat that it is a feeling which will be shared and sympathized with by the whole country.

In our own repeated visits to the Royal Farms,

in recording his success as an exhibitor, and in noticing the favourable auspices with which he commenced his year of office, we have from time to time testified to all the Prince Consort was doing for agriculture. His was not merely idle, passing patronage or casual aid, but it was rather a pursuit he delighted in, and one that he followed out with equal energy and advantage. The most practical man could not go that pleasant round from the Flemish Farm to the Norfolk, and so back again by the Home and the Dairy, without learning something wherever he went. The very last meeting which we believe the Prince ever presided over was that of the Agricultural Council in November; while the culminating point to such a career should have been but during the next few months.—Regarded either as one of the Arts generally, or more especially as a grand gathering of that Society he had consented to preside over, the Great Exhibition was undoubtedly growing from under the late lamented Prince's design and development. There is a settled gloom now cast over its prospects, from which it can never hope to recover, even if, under the circumstances, the project be proceeded with.—The bustle and crowd of a World's Fair will scarcely harmonize with the heavy heart of the August Lady, in all the fresh, bitter pang of her widowhood."

### The Agricultural Statute—Proposed Public Meeting.

The following circular has been addressed by the Secretary of the Board of Agriculture, to the County Agricultural Societies throughout the country, prior to their Annual General Meeting in third week of January :—

BOARD OF AGRICULTURE OF U.C.,

TORONTO, January 8, 1862.

SIR,—I beg to call your attention to the provisions of the Agricultural Statute, 20 Victoria, cap. 32, requiring each County Agricultural Society to hold its annual Meeting during the third week of January.

It is a part of the duty of each Society, at such Annual Meeting, under clause 11 of the Act, to nominate four persons as Members of the Board of Agriculture.

I beg to state, for the information of your Society, that the Board of Agriculture, as constituted last year, consists of the following gentlemen :—E. W. Thomson, Toronto; R. L. Denison, Toronto;

Hon. H. Ruttan, Cobourg; Asa A. Burnham, Cobourg; Hon. George Alexander, Woodstock; Hon. Adam Fergusson, Waterdown; Hon. David Christie, Brantford; and Wm. Ferguson, Kingston.

The four members who now retire are Messrs. Thomson, Denison, Ruttan, and Alexander; their retirement, however, does not render them ineligible for re-election.

The Statute requires each County Society to transmit, without delay, a certified list of the names and address of the persons nominated, to the *Secretary of the Bureau of Agriculture and Statistics, Quebec*.

I beg to remind you that a report of the last year's proceedings of each Society is required to be brought up and adopted at the Annual Meeting. It is desirable that these reports should be as full and complete as possible. The Act requires that they should contain a list of the members of the Society and the amount subscribed by each; a statement of the premiums awarded during the year, showing the amount, and for what and to whom awarded; such remarks and suggestions upon the Agriculture and Horticulture of the County, and Arts and Manufactures therein, as the Directors shall be enabled to offer; and a detailed statement of the receipts and disbursements of the Society during the year. The reports of the Township Societies are required to be transmitted to the County Societies in time for the Annual Meeting of the latter, and to be forwarded, along with the reports of the County Societies, to the Board of Agriculture, Toronto, on or before the 1st day of April. An abridgement of the Reports will appear in the Transactions at as early a day as possible.

I have to request that you will see that the reports of the Township Societies in your County, when they come into your hands, are complete in the several points mentioned, before forwarding them to this office, along with your own. I will also thank you to be particular to add to the report lists of all the officers elected for the present year, for both County and Township Societies, with the Post Office Address of each.

You will please observe that the names of members of the Board of Agriculture are to be forwarded to the Secretary of the Bureau of Agriculture, QUEBEC; and that the Annual Reports, &c., are to be trans-

mitted to the Board of Agriculture, Toronto.

I have to direct your attention to the following copy of a resolution adopted at the Annual Meeting of the Agricultural Association at London in September last:—

*“Resolved,—*That the Board of Agriculture are hereby requested to give notice to the several Electoral Division Agricultural Societies to send up each one delegate to attend a meeting to be held in Toronto the month preceding the meeting of the Legislature, for the purpose of agreeing upon and recommending such alterations as they may deem necessary in the Agricultural Statute, and that the Board of Arts and Manufactures, and delegates from the Horticultural Societies, be invited to attend; and in order more fully to carry out the spirit of this resolution, a synopsis of the Bill introduced at the last meeting of the Legislature be published, and a copy thereof sent to each County and Electoral Division Society, in order that the delegates may have a thorough knowledge of the subject under discussion, and that the travelling expenses (i. e. the fare for railway or other mode of conveyance, strictly,) of such delegates be paid out of the general funds of the Association, and that the President of the Board of Agriculture be authorized to name the day and place of meeting by circular.”

In accordance with the foregoing resolution I have to request that your Society will appoint one delegate to attend a meeting at the Board of Agriculture office, 188 King Street West, Toronto, at noon on Thursday, 30th January, inst., to take into consideration the above named matter.

The chief points in which the Agricultural Bill before Parliament last session differs from the Act at present in force, so far as relates to Agriculture, are the following:—

1st. A difference in the mode of electing the members of the Board of Agriculture.

Under the present Act each County Society annually votes for four persons as members of the Board, and the four persons who receive the highest number of votes from all the Societies in the Province, are thus elected for a term of two years; the number of elective members in the whole Board being eight, four of whom retire in rotation each year.

Under the Bill of last Session, Upper

and Lower Canada would each be divided into twelve agricultural districts; in each District each County and Township Agricultural Society would be entitled to vote for one person to represent the District at the Board of Agriculture, and the person who should get the majority of votes of all the Societies in a District would become the member of the Board of Agriculture for that District for two years. The number of elective members of the whole Board in each Section of the Province would be twelve, six of whom would retire annually in rotation.

2nd. The Agricultural Association as existing under the present Act would be entirely abolished under the bill of last session. There would be no delegates appointed by the Agricultural Societies to represent their views at the Annual Meeting of the Association, to elect officers, and vote for the next place of holding the Exhibition. There would in fact be no Annual Meeting, no Association, and consequently no members of the Association. The appointment of the time and place of holding the Exhibitions, and the management of all the business connected with them, would rest entirely with the Board of Agriculture, under its new organization, as above mentioned, and with the Local Committees which it might appoint.

3rd. The degree of connection which exists under the present Act between the Board of Agriculture, and the Board of Arts and Manufactures, in the business of the Annual Meeting of the Association, and in the general management of the Exhibition, would be abolished under the proposed Act. Each of the Boards would be empowered to hold Exhibitions, and it would be optional with them to hold them jointly or otherwise, as they might deem proper.

4th. The County Societies in Upper Canada heretofore entitled to receive a public grant amounting to \$1000; would under the proposed Act be entitled to receive a sum not exceeding eight hundred dollars.

5th. Under the proposed Act, of the amount granted for the encouragement of Agriculture, ten per cent in Upper Canada would be placed at the disposal and in the hands of the Board of Agriculture for the purpose indicated by law. It is not clear whether this ten per cent is to

be retained from the grants to the County Societies as heretofore, or whether it is to be received directly from Government, out of the amount of the Annual Grant for Agricultural purposes, prior to the apportionment of the grant to the Agricultural Societies.

There are some other minor changes in details, as to days of holding meetings, &c., which it is not important to mention at this time.

The delegate who may be appointed by your Society is requested to consider fully these proposed, alterations in order that he may be prepared to express his opinion upon their desirability or otherwise, or to propose others which he may think preferable, at the meeting here on the 30th inst.

I am, Sir,

Your most obedient servant,

HUGH C. THOMSON,

*Secretary.*

### Winter Management of Sheep.

[The following article is taken from that excellent monthly, the *American Stock Journal*, and will be found to contain many useful hints to all who keep sheep in these northern regions. While fully endorsing the writer's views of the necessity of affording sheep shelter during cold and stormy weather, we would caution the reader against confining them too closely. None of the domesticated animals, perhaps, suffer so much from a want of ventilation, and from close confinement, as sheep.]

1st. *Sheep should be sheltered.* That sheep require a good, clean, dry place, wherein they can be sheltered from storm, must be apparent to all who will reason a moment upon the subject. Storms, where the wool becomes saturated with water, not only impair their health, but wash out the natural yolk of the wool, necessary for its continued growth. All good wool raisers are agreed in this, and shelter and keep dry their sheep, especially in winter. The farmer will find himself abundantly rewarded by taking a little pains in this particular. And even if he has no sheds for his sheep to continually occupy in case of a storm, it is a good plan to turn the flock in upon the barn floor until the storm is over. It will richly repay him for his trouble.

In fact, I would rather my sheep should be shut up twenty-four hours, without food, than to be exposed to a long, cold storm.

By examining the fibres of wool upon the sheep's back, you will find them to be hollow, like the hair upon our heads. If these fibres are suffered to collapse by means of exposure to the snows and rains of winter, the growth of the wool is retarded, and it will take a long time, with the best care and treatment, for nature to re-open the fibres, and produce again that natural health and vigor.

Says a prominent wool-grower, "the advantages of housing sheep are manifold. 1st. A large per centage of deaths are avoided. 2nd. Much less food is consumed. 3rd. A much heavier and better fleece is obtained. 4th. The flock comes through the winter in a much finer condition. 5th. The lambs are more vigorous and likely to live. In short, reason, economy, and humanity, all conspire to teach the important lesson—*provide suitable stables for your sheep.* And he who can, and will not do it, ought himself to sleep barefooted and alone, on a couch of straw, with open windows, and under a leaky roof, where the winds go piping and careering through every crack of his cabin, for six months at least, until he shall have learned to sympathize with the dumb beasts God has committed to his care and keeping.

2nd. *Sheep should have water.* Many suppose that sheep can get along very well without water in winter, especially if they can get snow to eat. This is another very great mistake. Sheep do not drink large quantities at a time, but require it often; especially if they are not fed with roots. Just observe the operations of your sheep during the day, when fed with dry hay. They will run to the trough and take a few swallows of water, and then back to their hay, a number of times during twenty-four hours; and that too when the ground is covered with snow, showing that they prefer water to snow. Sheep undoubtedly will winter without water, but common sense teaches us that they cannot do as well without as with it, for the fluids of the system must be supplied to keep up a healthy organization. In Vermont, where water is plenty for all, and within the reach of all, that farmer who neglects this most important suggestion, should be considered a poor apology for a wool-grower, and should be compelled to go without himself a short season—sufficiently long to teach him that water is necessary for health and well-being.

3rd. *Sheep should be fed with roots.* That sheep require some kind of green or succulent food for winter use, I have demonstrated to my satisfaction. For a few years past I have fed potatoes and turnips to a portion of my sheep, and I know they have done much better than those which have been wintered without.

I raise some three hundred bushels of potatoes and one hundred of turnips, annually, which I cut up together, and mix in a little oat

meal or wheat shorts, and my sheep do remarkably well upon such feed. Especially is such food good for sheep about to have lambs, for it will make them have milk, should they lamb any time during the winter.

I think giving green feed to sheep in winter is generally overlooked by our farmers. European wool-growers consider this point of great importance. Morrell, in the *American Shepherd*, says, "The feeding of green food, such as potatoes, apples, hemlock or pine boughs, &c., is strangely disregarded by a large majority of American wool-growers. This is a prominent point of attraction of German management; indeed, it is thus in every section of the continent, where fine-wooled sheep are cultivated. The sheep, if placed in localities suitable to its general habits, at no period of the year is so perfectly healthy and thrifty as during the season of pasturage; and from this the inference should be deduced, that succulent food is the prominent inducing cause. Confinement to wholly dry food does not comport with that variety of condiment which has been urged so frequently, and consequently if a provision is not made of something else, it will be followed by disorganized action of the digestive functions, producing costiveness and constipation. The disease so frequent and fatal in American flocks, called the "stretches," results from costiveness; but this is scarcely known in England; which arises from the large variety of food the sheep are supplied with during the winter months. In addition to this, further proof may be found in the fact, that it is never known to attack the animal during the grass season. The writer speaks from personal observation, in stating that a supply of green food is indispensably necessary as a preventive of this disease.

In addition to green food operating thus, it has a tendency to increase the wool and yolk secretions, and thereby those valuable properties of wool, such as elasticity, softness and soundness, are increased and perfected; and withal, being conducive to health, the condition is improved, and consequently an augmented quantity of wool is a certain result.

These hints, though oft repeated, may have a tendency to do good if properly appreciated.

## Agricultural Intelligence.

### The Smithfield Fat Cattle Show.

This world renowned exhibition took place, as usual, during the second week in December, and for the last time at its old quarters in Baker street. A new Agricultural Hall is in the course of erection at Islington, a populous suburb of London, in which ample space will be found for the display of machinery, roots, seeds, &c., as well as enlarged quarters for increasing collections of fat stock. The show having so largely

increased of late years, particularly in the department of implements and machines,—a department not originally contemplated—that the premises in Baker street have been several times enlarged, still they are found altogether inadequate to present wants.

The following statement we have condensed from our excellent cotemporary, the *Mark Lane Express*, a paper that stands unrivalled for the copiousness and fidelity which characterizes its agricultural intelligence.

It appears that the society is in a very flourishing condition; and with more extensive accommodation, which it will have hereafter, a more prosperous future is anticipated. The prizes this year amounted to the sum of \$1,343 in money, and £160 in medals. For the future, the society is to receive £1000 a year from the Agricultural Hall Company for the privilege of holding its shows in that Company's new building, a picture quite novel in the management of agricultural exhibitions. The following table presents the number of animals of the different breeds for each year since 1854:

|                          | 1855 | 1856 | 1857 | 1858 | 1859 | 1860 | 1861 |
|--------------------------|------|------|------|------|------|------|------|
| Shorthorns . . . . .     | 40   | 42   | 43   | 4    | 47   | 36   | 50   |
| Devons . . . . .         | 17   | 21   | 32   | 28   | 37   | 33   | 33   |
| Herefords . . . . .      | 20   | 21   | 36   | 26   | 18   | 17   | 15   |
| Sussex . . . . .         | —    | —    | —    | —    | 15   | 15   | 15   |
| Scotch horned . . . . .  | —    | —    | —    | —    | 10   | 11   | 7    |
| Scotch polled . . . . .  | 16   | 13   | —    | —    | 13   | 5    | 7    |
| Welsh . . . . .          | —    | —    | —    | —    | 9    | 3    | 9    |
| Cross breeds . . . . .   | 7    | 12   | 64   | 35   | 17   | 19   | 8    |
| Norfolk . . . . .        | —    | —    | —    | —    | 4    | 4    | 4    |
| Longhorns . . . . .      | —    | —    | —    | —    | 4    | 3    | 4    |
| Irish . . . . .          | —    | —    | —    | —    | 1    | 1    | 1    |
| Extra Stock, &c. . . . . | 12   | 30   | —    | 40   | —    | 16   | 16   |
|                          | 112  | 139  | 176  | 171  | 175  | 163  | 169  |

It will at once be seen that the shorthorns are the only breed that have come up in greater number than was ever known before—making up nearly a third of the entire show. Devons, next in the list, stand at the old figure of last year, yet fewer than the year before that. Herefords have regularly and terribly decreased since 1857, and now are not one half as many as then. Sussex cattle are in equal force with the Herefords, neither more nor fewer for two years past. Scotch cattle are not so numerous as before. Welsh are a little stronger; but Cross-breeds amazingly reduced in number. Norfolks and Longhorns are but few, as usual. Irish put in but a solitary specimen, and extra stock animals maintain their common number of entries.

Of short horns it has been observed:

"We have often made complaints of the un-

finished condition of a considerable proportion of the steers and oxen of this breed: stalls have been taken up by too many plain animals—good butcher's beasts, but little more. Happily, there has been improvement in this respect; and good quality is now pretty well diffused among the numerous competitors for honors in the male shorthorn classes. Of course, we knew where to find the "Gold Medal" placard; for Baker street was not likely to turn out anything more wonderful than Mr. Taylor's Bingley Hall steer. Already has it been written of his touch not being quite so firm as one might desire, about his colour being a very light roan, and his tail being hardly set on square enough; but, in looking him over and over again, especially taking a front view of his magnificent chine, rib, and breast-end; of his broad, level back, without an inequality; of his handsome head, fine muzzle, and kind, docile eye—not forgetting his slender bone, that you may all but span below the knee—we can find very little to disagree with; and when we handle him, and look at him behind, we don't at all feel inclined to pick holes in his merit, or grudge him any bit of praise that he may win. Symmetry had never a fairer exponent than this. In depth of frame, too, he is uncommonly great; but in general grandeur and nobility of appearance, that air and expression marking some specimens of the breed, this steer does not, in our opinion, equal animals that have appeared for the Gold Medal. But let Bates blood have a share of the merit of this year's triumph."

The Devons in many instances combined splendid quality of meat with greater size than is commonly seen; and there were several useful animals of the Sussex breeds, originally derived from the Devon, but larger and coarser. Of Scotch cattle, there were some beautiful specimens, also of Welsh; but from Ireland only a single cow,—a genuine Kerry—wonderfully developed during her sojourn in England.

In SHEEP, three additional breeds have been introduced for the first time; the Romney Marsh (Kentish), Shropshire and the mountain. The Shropshires, which of late have been gaining reputation, were not so well represented as could be wished. Of the Kentish sheep it is remarked:

"The two pens of Romney Marsh wethers excited a good deal of interest, because they exhibited in the most impressive manner what could be effected by judicious selection. The flat-sided, narrow-chested, old breed, 32 months old, with loose flesh, barely covering a gaunt frame, gave an additional conspicuousness to Mr. Murton's short, square, stylish sheep, with deep expansive fore-quarters, and free curling fleece, there was just one year difference in age between them, Mr. Murton's having arrived at

greater weight of mutton in twenty months than Mr. Newport's in thirty-two. That improved breed is a hopeful sign. We hear that the French Government has become a customer to a considerable extent at Smeeth, having sent for several of Mr. Murton's rams to improve the breeds in the South of France. The clip is from 8 to 10lbs."

"The mountain sheep were quite the novelty of this part of the show. Every one made a point to look at the Exmoors, and the breeders of the Cheviots, have, we hope, learnt something to their advantage by their visit to Baker-street. They cannot avoid the conclusion that a cross with a breed which comes to a greater weight, both as respects wool and mutton, in a year less time than is usual with the Cheviots, is a matter that must be looked to. We shall be glad to hear of some transactions between Mr. Quartly, Mr. Tapp, and Mr. James Hole, and the breeders of the North; for surely such an opportunity should not be missed by men of enterprise. The tendency of the meeting of the Club to bring men together to increase the produce of the country could not be better illustrated than by the pens under revision. Not only may the breed of mountain sheep be improved, but the hill-side pastures will be increased in value. The Cheviots were not the only sheep to be benefited by the cross. The big black-faced mountain sheep from Aberdeen were by their side, older in years, and larger in frame; but still the contrast was in favour of the ripe little Exmoors, so impudent and amusing, sitting on their hind legs like little dogs. Epicures need not entertain any fear that they will lose the fine flavour of the mountain mutton; there will still be haunches of as undeniable quality as ever encountered the heat of fire or criticism, while the hill country shepherd may have a chance of quickening his returns, and mountain pasture will rise in value."

The long-wooled breeds appear to be increasing in reputation daily; they made a splendid show. Mr. Foljambe's pair of three 20 month's old wethers, commanded great admiration. In forequarter they were wonderfully developed, two girthing 5 feet 7 inches, and in style and look were all that could be desired and for quality their wool was as remarkable as the other points. The following remarks are suggestive:—

"The classes for cross breeds are always interesting, and should ever form an important point in fat stock shows, because of the disposition of such animals to feed quickly. This tendency was specially observable in the cattle classes of last year, and was notable, though not so much so, in the show just closed—the cross between the Shorthorn and Polled Angus, the Shorthorn and Aberdeen, and the Hereford and

Shorthorn. The cross breeds of sheep were more remarkable this year than they have ever been, and we have seldom seen so wonderful a display as that made by Mr. John Overman, in the two classes with wethers, that were the result of his favourite cross between the Leicester and Southdown. Mr. Hine, too, made a grand display, and followed Mr. Overman in both classes. In the Extra Stock, the Oxford Down wether, an original cross between the Hampshire Down ewe and Cotswold ram, but now considered, by virtue of age, an established breed, took the lead with a grand sheep exhibited by the executors of the late Samuel Treadwell. Looking at these Oxford Downs from a consumer's point of view, they certainly seemed to abound in more good flesh than their more favored rivals, the Leicesters and Sussex Down cross, which though wonderful for rump, back, and plate, struck us as having the fat too predominant, and too unevenly distributed through the body. Mr. Overman's are large sheep, with a great display of the Leicester; while the Oxfords, already mentioned, and Mr. Druce's, which took a third prize, showed dark faces and wool, a large square frame, and fine quality. We preferred their head to that of the Leicester Down cross, as evincing a more high-toned and vigorous constitution. Mr. Oakley's cross between the Hampshire and Gloucester resulted in a most useful class of sheep, the only defect of which was in the thigh. Mr. Hine's small and pretty cross between the Down and Leicester were remarkable for fine bone and reduced offal; while Lord Berners' Cotswold and Leicester cross showed special merit."

In Pigs the show was, as usual, extensive, comprising animals fattened to the highest degree of the various breeds now cultivated in England. The implement department embraced most kinds of agricultural mechanics in their present improved forms. Next year will afford in the new building ample space for progress in increase in every department of this important and well-known institution.

We clip the following extracts from addresses made by members of the club at the annual meeting and dinner, which will be both interesting and suggestive to many of our readers.

"Mr. Barford moved the following resolution: 'That in future any sheep that may be exhibited for any prize offered by the Club, shall not be in any way clipped or trimmed (except on the head and legs,) and any sheep so clipped or trimmed shall be disqualified.' He said he considered that the present practice was based on a bad principle, and that the exhibitors deceived themselves in resorting to the system of clipping. A few years ago the Prince Consort, during a visit to Birmingham, called attention to a principle which he justly said was forcing its way

into society, namely, the introduction of science in art as the conscious regulator of production. In all their operations, said his Royal Highness, whether agricultural or manufacturing, it was not they who operated, but the laws of Nature which they had put in operation. Now, the clipping of animals into form was a departure from a law of Nature. When he was elected a member of that Club three years ago, he felt that its object was to encourage the breeding of those animals which would pay best, and produce the most nutritious food for man. It might be right and proper that a few animals should be exhibited in that extraordinary way, in order to show what state they might be brought to; but after having paid much attention to the matter, he had arrived at the conclusion that animals used in a lean state would always produce better stock than they would when then they were in a fat condition. A few Exmoure sheep were exhibited in the yard that day. They were a new class in the show; but as regarded quality, he fancied that there was more nutritious matter in one pound of those animals than in the same quantity of any other description of animals in the show. His only motive in moving the resolution was that the matter should be put on a sound footing. He was of opinion that every man who had been in the habit of clipping would do better to study anatomy and the laws of Nature than the art of deceiving."

This motion was lost by a vast majority; Mr. Fisher Hobbs remarked, "that if there was any one point in the animal that ought to be in a perfect state of nature, it was the face and head. In the Royal Agricultural Society such restrictions as that now proposed were abolished twenty years ago."

Mr. Torr, a very extensive Lincolnshire grazier and farmer, in returning thanks for the judges, congratulated the members of the Club upon the successful show in Baker-street during the past week, the merits of which he and his colleagues had a better opportunity of testing than any other parties. Whilst not so good as former ones in some classes, upon the whole it was a successful show. He was bound to say; that the Devons deservedly kept their place, that the Herefords were hardly up to the mark, and that amongst the Shorthorns there were certain shortcomings. Indeed, he thought they were very much indebted to Mr. Taylor, the winner of the Gold Medal, for the best oxen in any of the classes, for saving their credit, as he might also say, on the present occasion; for they might depend upon it that if his ox had been taken out of the show, a large plum would have been abstracted from the pie. With regard to the heifer class of Shorthorns, he would take the liberty of advising his Shorthorn friends to use more exertion, or they stood a chance of losing the Gold Medal which they had so con-

stantly carried away of late years. He supposed however, the real fact to be that this description of stock had become valuable, and was making such fabulous prices as lean stock, that still less would be seen of them here in future. The cross-breeds in the show were the best he had ever seen, and the Scotch cattle were pre-eminently good. Another class in which he himself felt a little interest was the Leicesters; and he thought the Leicesters never cut a better figure, or the long-wools taken altogether. As to the Southdowns, continued Mr. Torr, why they have got so perfect that there is no use to talk about them; while the pigs are, as usual, wonderful! As a judge, he regretted to say that of late years the practice had grown up of judging animals too much by tape and two-foot rule. Now, for his part he could not see much value in applying any such test. A bullock or sheep was not like a brick or piece of iron, cast in a mould, so many inches long and so many inches wide and deep. There was intuition, an innate taste, in all judging—something in a man's brain who had been nurtured and brought up as it were with stock, a principle within him which, if it were right, would make him a good judge. That man would form his opinion from the character of the animal, and something else perhaps which he might be unable to describe in words; but as to these measurements and computations, he had lived long enough in the world to know that they were of very little worth. He had tried all sorts of measurements in his time, but he would rather take the result of his friend Mr. Giblett's glance than all the measurements in the world as to weight (cheers); and as to character, give him the man who had devoted himself to one particular breed; but do not choose him to be a judge of any other."

Mr. Brandreth Gibbs, the honorary Secretary, to whose long and indefatigable exertions the Club is greatly indebted, in returning thanks observed:—

"He need say but little with regard to the present state of the Club, after what had been said by those who preceded him; but when he told them that they had a balance of more than £3,000 in addition to £1,500 of invested surplus annual income, and £700 more to receive on the following day in Baker-street, and that there was only about £1,500 to be paid out of all this for prizes, they would perceive that the Club was financially in a most satisfactory condition (cheers). It is now twenty years since the Club met in a small livery-stable yard in Smithfield. With its progress since they were all familiar. There had been two great eras in its existence: the first was its formation; the second was its removal to Baker street. From the latter its prosperity might be said to have dated. Its increase had since been progressive, and from having only £300 for a very limited prize list, it was now enabled to offer the

large amount he had mentioned. Although they were going to a magnificent hall, he should often look back with feelings of great satisfaction to Baker-street. Baker-street and the Smithfield Club had in his mind long been associated together. During the eighteen years that he had been the honorary Secretary, it was there that he had worked, and he should often have most pleasing recollections of the past. As regarded the future, he could only say that he looked forward to a still more brilliant career for the Club, and that no exertions should be wanting on his part during the coming year (loud cheers) to render the first meeting worthy of the inaugural show of the Smithfield Club at the Agricultural Hall.

### The Royal Dublin Society,—Winter Show.

This important Society, which has been established, we believe, upwards of a century, held its Winter Show on the 18th and 19th of Dec. in the very extensive and convenient Hall, Kildare Street, and every portion was fully occupied by the different departments. The weather was most favorable, and the attendance of visitors very good. We abridge the following statement from our talented cotemporary *The Irish Farmer's Gazette*, a paper which, for the soundness of its practical views, must exercise a very beneficial influence both on the agriculturist and the agriculture of the lovely Emerald Isle.

It appears that the greatest portion of the now considerable income of this venerable society is devoted to arts and manufactures, and the *Gazette* loudly, and it would seem justly, complains of the comparatively little encouragement to agriculture, particularly at the Winter Shows, and the agricultural interest seems but feebly represented in the Board of management. This is an unfortunate mistake, as Ireland upon the whole is by far more decidedly agricultural than any other portion of the United Kingdom, and the resources of its soil, particularly for stock raising, are immense. Still the turn out of stock is said to have been astonishingly good on this occasion; and the report furnishes a number of animals both of pure and mixed blood that evinced excellent points, and would yield beef of the best quality. Sheep were well represented, particularly the long woolled, and Mr. Allan Pollock seems to have greatly distinguished himself in this department, as he did among cattle.

"Pigs are getting scarce in Ireland—a fact

which the *Times* considers one of the best evidences of our improved circumstances; and the fat pigs were not so numerous as they might have been. But there were some choice ones among them, particularly a very nice lot of thick, symmetrical, tempting little pictures of the small Yorkshire breed."

There were also some fine specimens of the great Yorkshire breed, as also Berkshire, Middlesex, &c. In Poultry the show was very good, particularly the Dorkings, Cochins, also Turkeys and Geese. "The Geese had immense birds to represent the class, among them a pair of *Canada Geese*, which were greatly admired, and no doubt, can be easily domesticated, and, as they weigh as much as twenty pounds, deserve attention."

In vegetables the show appears on the whole not very extraordinary. The soil and climate of Ireland, it is well known, are admirably adapted to the growth of root crops. The following extract contains some matter worthy of more attention on this side the Atlantic:—

"It is conceded that the prize mangels particularly were somewhat coarse, and some would have it that the prizes in roots should have been awarded to some specimens more cleanly grown; but the fault of coarseness was more or less apparent in all those exhibited, and it was calculated that if all had been trimmed so as to remove every portion over and above the solid roots, that the largest specimens would still carry the weight. However this may be, it would be a great improvement in the list of prizes for forthcoming shows that a prize would be given to the cleanest grown specimens, irrespective of, but up to or beyond a certain average weight. We must again in this general notice, refer to Lord Claremont's magnificent collection of farm produce, which amounted in the aggregate to several tons weight, and so numerous were the groups as to leave no doubt on the visitor's mind that the general crop could not be much behind the specimens exhibited, and it would be impossible for any single exhibitor in Great Britain or Ireland to exhibit such a collection, or that exhibited by J. J. Radcliffe, LL.D. Both Mr. Brady, Lord Claremont's steward, and Mr. Linahan, Mr. Radcliffe's steward, acknowledge that the superiority of their crops is owing chiefly to the after dressings of Phospho-Peruvian Guano they received. The following very concise and graphic description of Mr. Brady's mode of improving the land at Marino and cultivating the crops was appended to Lord Claremont's collection, which must be of considerable use and interest to some of our amateurs and less practised agriculturists:

"The original depth of *active or surface soil* of the land which produced the greater portion

of the items in this collection was scarcely seven inches; the subsoil a yellow clay, recumbent on a gravelly bottom. The annual produce of it in its reclaimed state, either in grass or in tillage, was scarcely worth £8 per Irish acre.

"It was thorough-drained at a cost of £4 10s. per acre, and subsoiled with the spade at £8 per acre.

"In subsoiling it, the *subsoil was not turned up*, and the *active soil all turned down*, but the subsoil was broken and loosened to the full depth of the pick and spade, and left lying on its own bed, and the active soil turned over it, *upside down*.

"The work commenced in December, and was finished by the beginning of February.

"In the last week of April the ground was thoroughly pulverized with Graham's deep grubber, and a portion of the broken subsoil well incorporated with surface soil. It was harrowed and rolled, and the mangel seed all sown by the 1st of May.

"The turnip ground was similarly treated, and the seed sown by the first week in June.

"The manure for the mangels was 35 tons of well-prepared compost and 4 cwt. of phospho-Peruvian guano per acre, and the produce not less than 90 tons per Irish acre.

"For the turnips, 30 tons of compost and 4 cwt. of phospho-Peruvian guano, and the produce 70 tons per acre.

"P. S. — Whoever doubts this statement, I shall be happy to meet him here. He can see the ground and the produce, and judge for himself.

"JAMES BRADY.

"Marino, 13th December, 1861."

The show of agricultural implements and machinery is described as of a superior character, deserving of the highest commendation and support. Many of the principal English makers were well represented, but, from some cause which does not appear, the Irish manufacturers, who now produce some first rate articles with all the appliances suggested by modern mechanical ingenuity, appear to have been but few. The report thus concludes:

"The whole central hall was crowded with the machines and implements exhibited. The frieze was exhibited on the galleries; but we have to remark that though our English friends have come forward as usual, and in great strength and power, at vast expense and loss of time—for which we hope they may be fully remunerated—we regret to find none of our Irish agricultural implement makers have done the show or the *Public* the honor of exhibiting their implements, with the single exception of Ritchie, of Ardee. Polished steel breasts or mould-boards for ploughs are now common in England; they

are much lighter than the cast iron ones, last longer, and are so perfect in form that they run through the land lightly, and with much less draught on the horses. We don't see why the Irish manufacturers should not adopt them; they are cheap, and every way superior to the common metal ones. Verily, the native manufacturers must look to their laurels; they have won them fairly in several well-contested fields, but that is no reason why the Irish farmer must still kill his horses in dragging through the soil a heavy implement, when modern art and science have supplied him with a better and as an enduring an article."

### Profits on a Poorhouse Farm in Ireland.

It would appear that in most parts of Ireland the harvest of 1861 was deficient both as regards quantity and quality, the growing season having been accompanied by incessant rains and a low temperature; conditions unfavorable to root crops, and oftentimes absolutely destructive to cereals. Hence we hear of a large portion of the potato crop being entirely destroyed by disease, hay spoiled, turf insufficiently dried for the purpose of fuel, and the ordinary produce of grain diminished, and its quality deteriorated. This gloomy future, there is ground for believing, has been somewhat overdrawn by certain individuals for party purposes, but it undoubtedly remains a fact that in this part of the United Kingdom, and also in Scotland, the unfavorable weather during the greater portion of last year, has been attended by very serious consequences to the farming interest.

Notwithstanding the husbandman must always continue in a great degree passive under whatever may, in the order of nature, be the character of the season, it is cheering to know that the tendency of our modern improvements is to provide him with a power, which, within limits not yet ascertained, enables him in some manner to modify the bad effects of unfavorable seasons. Thorough drainage and deep culture, for instance, will now often carry crops well through either a drought or an excess of moisture on soils where, before these ameliorating agents were introduced, they would have inevitably failed. Improved husbandry therefore gives us *improved*, if not equal crops, in bad seasons as well as in good. This great and encouraging truth we should study to keep constantly in mind, as the basis of every advancing

farmer's creed; and which is happily illustrated in the following statement of facts, which we take from the December number of the *Practical Farmer's Chronicle*. The writer in speaking of the good results produced by a suitable education in connection with improved cultivation, remarks:

"In proof of this, one example out of many others we could give, may suffice for the present. That we select is from the Poor-law Union of Enniscorthy, in the county of Wexford, and Province of Leinster. It is the only union in Ireland, to whose poorhouse is attached even the small quantity of land which the law allows. All, unfortunately, must now admit that the corn crops of this year are deficient in quantity in England, as well as on the continent; and under circumstances favorable, compared to Ireland, where the chief grain, and even some of the most important green crops, are all but a total failure; yet here, on this poorhouse farm, because of its superior management by the labor of paupers,—boys, the old at not over 14 years of age,—the culture of the grain crops, and some of the green crops, have produced the following results:—

| CR. |    |    | £                | s.  | d.    |
|-----|----|----|------------------|-----|-------|
| A.  | R. | P. |                  |     |       |

| Rent .....                                                                                                                |  |  | 90   | 2  | 10 |
| Labor; wages of Ploughman ..                                                                                              |  |  | 20   | 16 | 0  |
| Taxes, purchase of implements, repairs of same, Machine for threshing corn, artificial manure and other incidentals ..... |  |  | 79   | 11 | 8  |
|                                                                                                                           |  |  | 190  | 10 | 8  |
| Balance to credit of Farm .....                                                                                           |  |  | 283  | 2  | 8  |
|                                                                                                                           |  |  | £473 | 2  | 8  |

Comment on the foregoing would now be needless beyond this; that in some wheat lands in Ireland, far superior to the Enniscorthy land, the value of the wheat crops did not amount to *one fourth* of the value as above; on better oat lands, the proportion is equally low; whilst the mangel wurzel and carrot crops in Ireland are all but a total failure. Even the Swedish turnip crops are exceedingly inferior, on very superior soils; whilst, on some of the best meadow

lands in Europe, the low, rich lands of the midland counties of Ireland, the hay crops have been rendered valueless, except for dung manure. But why these superior results obtained at this poorhouse farm? Because (1) the land is partially—yes, and *but partially*—drained to render it fit for being worked; (2) because it is worked as it ought to be, comparatively speaking; for though *practice* is brought well to bear on it, science has not yet done enough to advance the interests of the farm, or promote the education of the boys.”

The above facts clearly show something of what yet remains to be achieved for the agriculture of the Emerald Isle by the happy union of capital, science and improved practice. And when more of our Canadian forests shall have been brought under the subjection of our rude methods of tillage, who can calculate the millions which our soil will then be capable of supporting, by the use of those necessary means for effecting its full agricultural development?

### The Birmingham Cattle Show.

The eleventh Exhibition of this Society, embracing chiefly the midland counties of England, was held in the spacious Hall of the association on the 2nd 3rd, and 4th of December. Every year this Exhibition has been gaining ground, the total number of entries the first show being 901, while this year it reached the largest aggregate ever attained, 2055. The prize list now amounts to £1,300, not including the value of medals and a large number of special premiums. We take the following facts from the *Birmingham Daily Post*.

The Herefords, which are well known for their fattening propensities, appear to be falling off in numbers at this Exhibition. In 1859 they reached 32; in 1860 they fell to 25; and this year are only 21. They were, however, remarkably good in quality, flesh bearing points being strongly developed. The cows were excellent. His Royal Highness Prince Albert, was a large exhibitor in many sections, and usually more, or less successful with this breed, got only a “commendation” for his steers. Mr. Shirly of Bawcott, Salop, a most distinguished breeder, got the first prize of £10, the Society’s other prize of £20 for the best Hereford in the yard, and the Presidents £25 cup for the best ox or steer of any breed or age, fed and bred by the exhibitor. The Herefords carried away two out of the five grand premiums.

In Shorthorns the competition was much greater than on previous occasions; numbering only 29 in 1859–60, but reaching to 45 in 1861, and their general quality ranged extraordinary high. Earl Spencer was among the most successful, but Mr. G. Taylor of Bridlington, York-

shire, appearing for the first time in Bingly Hall arena, at once reached to its highest point of honor. He obtained the £10 prize of the class; the extra prize of £20, for the best Shorthorn Exhibited, and the Society’s Gold Medal for the best ox or steer in the yard. The class of cows is described as extraordinarily good. The Devons were few, but of high quality, the first prize for cows was taken by Prince Albert. There were only four entries in Longhorns. In all the crosses there was a strong infusion of short-horn blood, the examples of which presented striking points of excellence. Of the Scotch breeds there were only six specimens, the expense of transit so great a distance will likely keep this interesting class small. Mr. W. McCombie, of Tillyfour, Aberdeen, carried off the honors for both oxen and cows, firmly maintaining against all comers the position which he has for some time held of being the most successful breeder in this department. His prize Galloway cow was pronounced the gem of the collection. She obtained the £10 prize of her class, the Society’s Gold Medal for the best cow or heifer, and the Hotel and Inn-keepers’ twenty guineas cup for the best animal of any class in the yard. She measures 8 feet 8 inches round the girth, and her fulness and truth about the hind quarters are the points in which she is supposed to have vanquished Mr. Taylor’s short-horn steer in the contest for general superiority over the whole yard. The show contained several admirably fattened specimens, perfect beauties in fact,—of the Aberdeen and West Highland breeds.

The sheep mustered in larger numbers (68 Entries) than in former years and the competition was stronger, but the general excellence, perhaps, was scarcely equal to some previous occasions. Mr. Foljambe’s Leicesters were splendid specimens of fat sheep both in point of weight and symmetry; and the Duke of Richmond and Earl of Radnor showed some South-downs which commanded universal admiration. In the number of pigs the show was even less than last year, but what were brought forward were very superior animals both as regards breeding and fattening. His Royal Highness the Prince Consort was a very successful competitor in this department. The display of poultry was very extensive and superior; Mrs. Fergusson Blair, of Scotland, carried off numerous prizes in this department. Her silver gray and colored dorkings, white Cochin China, and B. amah Pootra, are said to have excelled anything ever seen on such occasions. This lady has written a very popular treatise on Poultry, which she treats both philosophically and practically in a most winning and useful manner. In point of numbers, and the proceeds of the gates, the show must be considered a distinguished success.

A new feature accidentally connected with this Exhibition deserves to be mentioned. Two years ago the Birmingham Cattle Show was chosen as affording the fittest opportunity for launching a new project, an Exhibition of *Dogs*.

Some 80 or 90 were entered for competition and a considerable interest was excited; while this year the entries exceeded 500, and the animals exhibited, while embracing the blood of the best kennels in the kingdom, also represented the almost endless varieties of those breeds not devoted to field sports at all. The handsome sum of £450 was given in prizes, besides a considerable amount of extras. A similar exhibition took place at Leeds during the show of the Royal Agricultural Society of England last July, and in London and other places, we believe, Dog Shows have been attended by a success and popularity hitherto unexpected.

### The Potato Disease.

An English writer comes to the following conclusions in regard to the potato disease. We publish them for the consideration of our readers.

1. The desirability of early planting in dry, clean, and well prepared ground.

2. The white potatoes are less liable to disease and are therefore to be preferred to the colored sorts.

3. That the soil in no case produces or influences the disease.

4. That the disease is of a fungoid character, infesting many varieties of plant, and increased in activity by atmospheric causes.

5. That all heterogeneous manures are injurious.

6. That lime and salt, mixed in the proportion of eight tons of lime with three cwt. of common salt is the best manure; and this is the proportion used to the acre.

7. That potatoes that ripen the earliest should be exclusively grown.

8. That, as soon as the disease appears, earthing up the stalks repeatedly with fine earth from the centre of the trench is the only effectual preventive to its ravages. To this operation the author attaches the greatest importance.

9. That when exhumed, sunlight appears to arrest the progress of the murrain, and prevents the further decomposition of the tuber.

### Hoeing Doubly Useful.

Hoeing between crops, in the garden or the field, when properly performed, accomplishes at the same time two of the most important operations in cultivation—namely, the destruction of weeds and the pulverization of the soil. The scratching and scraping with the Dutch and draw hoes, as is usually performed, no doubt cuts the young weeds to the surface, and in this way gets

rid of the annuals, but many biennials and most perennials, instead of being destroyed, are rather strengthened by the operation, while the pulverization of the soil is not effected beyond an inch in depth. If hoeings were commenced when weeds have only made their cotyledon leaves, say from half an inch to an inch in height, and were the Vernon or Spanish substituted for the Dutch and draw hoes, the weeds would not only be completely eradicated, but the soil would be loosened to the depth of six or seven inches. Another advantage the Vernon or Spanish hoes have over those in modern use is, that the operation may be performed between rows of root crops without injury to the tubers or bulbs, which often sustain great injury from being wounded by the others.—*Scottish Farmer*.

**HOME-MADE BONE MANURE.**—A. F. G. of West Gardiner, Me., writes to the American Agriculturist that he makes a good bone manure thus:—A kettle holding a barrel or more, which is kept for boiling roots for stock, is filled with bones, and caustic lye poured in to cover them. A gentle fire is built for two or three successive days, to barely warm the liquor through. In a week the bones become soft and fine. The mass obtained from one barrel of bones is then mixed well with about three loads of muck, the leached ashes from which the lye was obtained, being mixed with the heap. After lying awhile for the muck to partly decompose, the fertilizer is ready for use, and produces good effects.

### The late Lord Berwick's Sale of Herefords.

The great HEREFORD SALE at Cronkhill, as we learn from our English exchanges, resulted as follows:

|                                                   |           |
|---------------------------------------------------|-----------|
| First day, 104 head old and young, sold for . . . | £2959 17s |
| Second day, 42 heifers . . . . .                  | 1,018     |
| 34 bulls . . . . .                                | 1,353     |

Being an aggregate of 180 head, in round numbers, of about \$26,800, and an average of not quite \$150 per head all round—about \$135 per head for females, and about \$195 for males. The highest prices paid were 100 guineas for the bull "Retribution" and 70 guineas for the bull "Caning" both to go to Australia. Several head were purchased for Fred. W. Stone, Esq., of Canada West, who was the only purchaser whose name we find as coming from this side of the Atlantic; his purchases were Jenny, for 26gs.; Agatha 30gs.; Graceful, 23gs.; Wild rose and Sweetheart, heifers, at 40gs. each, and the bull Sailor at 20gs. Among other purchasers, were Col. Hood for the Windsor farms of Prince Albert, and many prominent land owners and occupants of the neighborhood. The prices are probably all that could have been hoped, on so

large a sale, while they are very possibly below the standard of value at which the late Lord Berwick would in many instances have rated the individual members of the herd.

The sale also included a flock of about 600 sheep, chiefly Shropshires—about one-half breeding ewes; “a lot of handsome white Berkshire pigs;” some dairy cows and heifers, and half-a-dozen Bretonne Cattle.

**RECENT ENGLISH RAM LETTINGS.**—The ram lettings in the eastern counties continue to show, as stated recently in the *Times*, a great development of enterprise on the part of sheep-breeders and the agricultural interest generally. At the letting of the Tethwell rams, for instance, the 117 offered made a total of £1200, being an average of £10 7s. each. The highest price for shearlings was £27, and the highest price for two shears and upwards was £55. At the annual Biscathorpe ram-letting, 120 fine animals were offered, and several of the shearlings were let at prices ranging from £20 to £30 each, one lot realizing £42, another £50, and a third £71. The two and three shears also went off well, three lots making upwards of £30 each, and another lot £52 10s. The shearlings averaged £15 13s. 4d., the two shears £14 1s. 10d., and the three shears £14 14s 7d each. The total sum realized for the 120 lots offered was £1786 10s., and the average was higher than at any previous letting at Biscathorpe, having been £14 17s. 9d., in 1861 £13 12s. 6d. in 1860, £14 14s. in 1859, and £11 9s. 4d. in 1858. Mr. William Torr, another well-known Lincolnshire breeder, has held his letting in the course of the last few days, and offered 40 shearlings, 24 two-shears, and 26 three-shears and upwards. For some reason best known to himself, Mr. Torr,—who is known throughout England as “Torr of Aylesbury”—did not conduct his letting publicly, but put his rams off by private contract. It was stated, however, that the average price obtained was satisfactory. Taking into consideration the increasing prices paid at these lettings, there seems little reason to doubt that the agricultural interest, notwithstanding the unfortunate harvest of last year, is still in a satisfactory and buoyant condition, and has abundant resources at command. The good prices obtained for meat and wool have caused additional attention to be devoted to the production, and hence the high prices willingly paid for first-class rams, from which sheep calculated to yield the utmost possible amount of mutton and the heaviest fleeces are likely to spring.—*The Field*.

### European Shepherds.

In Spain where the celebrated Merino flocks are bred, there are ten millions of sheep to be led, twice in the year to a great distance in search

of pasture, or a warmer climate. Forty or fifty thousand shepherds guide these sheep in their wanderings, and travel with them many miles.—Those shepherds have a very hard life; but they would not leave them, even if they could get better pay and less work elsewhere. As many as thirty thousand dogs accompany the flocks in their wanderings, and put up with hard fare like their masters. The Spanish shepherds live chiefly on bread seasoned with oil or grease; and though they sometimes procure mutton from their old and diseased sheep, it is not their favorite food. Their dress is a jacket and breeches of black sheep-skin, a red silken sash tied round the waist, long leather gaiters, a slouched hat, a staff with an iron point, and a *manta* or brown blanket slung over the left shoulder. When they have reached their journey's end, they build themselves rude huts, living generally in single life. Large flocks are managed by several shepherds, and that everything may be done with regularity, one of the most experienced is set over the rest. The times of their wanderings are in May and September, and the whole journey is that which has been taken for ages. The sheep know the way as well as their masters: and a free passage is granted to them through pastures, villages, etc., where the inhabitants are obliged to leave an opening for them, at least ninety paces wide. The shepherds on their part have to leave them as quickly as possible, that they may reach certain resting-places where they find an open space and good pasture.

In some parts of France the shepherds live a similar life. More than a hundred thousand sheep graze on the plains of Arles in winter; but as the spring approaches they show the greatest eagerness to set off towards the mountains bordering on Italy: and if not watched, they will escape and be lost. The shepherds set out in May for these mountains, driving their sheep in troops of from ten to forty thousand. To every thousand sheep three shepherds are allowed; each of which has his dog, and in the middle of the flock a troop of asses carrying baggage. A chief shepherd is chosen, by the general consent of his companions, to direct the march, to deal out the daily share of provisions, and to listen to the complaint of farmers, when damage is done upon the road. The shepherds' dogs are assisted in a remarkable way in keeping these large flocks in order. The goats are especially trained for the purpose, and have bells around their necks. They are kept in perfect discipline by the shepherds, and show great intelligence in the performance of their task. They halt or proceed at the word of command, and at the close of each day's march, they come to the centre of the flock, and wait there until the morning, when, having received their proper orders, they return to their station at the head of the flock with the greatest regularity. (On coming to a stream, they halt until the word of command is given, when they plunge into the water, and are followed by the rest of the flock.

When the flock reaches the mountains, each shepherd has his proper boundary marked out, and the proprietors of the land are paid about twenty pence per sheep for their feed during the Summer. The shepherds sleep with their flocks in the open air, and live almost entirely on bread and goats' milk.

In the south-west of France, on those wild plains called *Les Landes*, the shepherds lead a very singular life. The country consists of large tracts of deep sand, or of marshy ground, with scanty herbage and prickly shrubs. That they may cross these sands without difficulty, the shepherds fasten stilts, or wooden poles five feet long, to their legs, putting them on and off as regularly as any part of their dress. When their flocks are grazing, they do not take off these stilts, but remain elevated upon them that they may the better watch their sheep. The top of the long staff which they use in walking is made broad and round, so that they can sit upon it. Thus seated they knit stockings all day, and, clad in her rough sheep-skin coats and caps, they have a most singular appearance, looking like so many little watch-towers scattered over the country. The rate at which they can travel on these tall stilts is sad to be equal to that of a trotting-horse.

Some of the sheep-owners in Australia possess fifteen or twenty thousand sheep, and these are led out to graze before sunrise, and folded or brought back to the sheep-yard at night. The wild dogs of that country are great enemies to the sheep, and will sometimes fall upon them in the open day. The shepherd is, therefore, always on the watch; and in setting up his fold, he uses hurdles made of slender rods of iron or oak seven feet long, and so close together that the lambs cannot escape, nor dogs enter. By the side of this fold he places a moveable, weather-tight hut, in which with his dogs he passes the night, keeping a fire burning near the hut to scare away the wild dogs. He has also to watch against a more crafty foe in the escaped convict, whose retreat into the interior of the country is said to be usually well stored with mutton stolen from the different folds.

## Horticultural.

### On the obtaining of a New and Superior Parsnip from the Wild Species.

As the origin of some of our common cultivated plants has been considered by some to be a matter of extreme mystery,—a few (a very few) among botanists, holding the notion that such really have descended to us from the Garden of Eden,—we shall here give an account of some successful experiments in the ennobling of the wild parsnip, in order, if possible, to point out the principles connected with the development of these useful roots.

Professor Buckman, of the Royal Agricultural College, Princeton, in the autumn of 1847, gathered some seeds of the *Pastinaca Sativa*, (the wild parsnip) which was sown in the following spring. On coming up, the plants were *thinned*, and when sufficiently advanced it was found that most of the plants had the hairy, dark coloured leaves, with narrow segments, of the ordinary wild plants. Amongst these, however, were a few plants with the leaflets larger, a brighter colour, and smooth, like those of the cultivated examples. These latter, then, were left for the crop; and in the autumn of the same year the roots were taken up, and the best of them *stod in sand*, to be transplanted for the growth of seed.

Many of the second generation from the wild stock showed, on coming to maturity, more or less of improvement, on the small, wiry root of the wild species. Some of them had a generally clear, well-shaped outline, with a few lateral roots, whilst the foliage had assumed the form and colour of the garden parsnip. The objectionable lateral roots were in reality examples of finger and toe, which in a cultivated parsnip is sure to be derived from a degenerate stock; but, just as in the crop parsnip, this tendency may be considered as the sign of degeneracy, so in the present case it was viewed as an evidence of advance to a better form from the *wild state*. The selection of the best of these for seed, and again selecting in like manner from the produce, in ten years resulted in the production of a new variety of parsnips, possessing the following advantages:

1. A more perfect outline, as being free from finger and toe.
2. A better flavour than the ordinary parsnip.
3. As being of a newer sort, and as yet not degenerated in constitution from repeated cultivation in the same soil, it may be expected to be freer from tendencies to malformation or disease.

Professor Buckman found that this parsnip in form was all that could be desired, its root remarkably clear and straight, free from lateral branchlets, and its flavour such as to render it the best of all cultivated varieties. He gave it the name of the "*Student*;" and finding it impossible to continue growing it in the same soil without degeneracy, he assigned the seed to the well-known nurserymer, Messrs. Suttor, of Reading, who have grown it with great care, and the following is their report of their crop of 1861:

"We are happy to tell you that, in lifting some of each of the varieties of parsnips in our trial ground, your "*Student*" was decidedly the best shape, varying in length, but always clean and straight."

Such testimony then is good evidence of the value of this new form of parsnip, whilst the case, as we have detailed it, cannot fail to be interesting to those who would study the origin of our esculent vegetables. If the points before mentioned, gathering seed and sowing it in pre-

pared soil, selecting and preserving roots for the next generation, and so on, be attended to, most plants will get a new nature therefrom, and such experiments will soon show us that plants as esculents are the result of such cultivative processes; and when these are not attended to, they either die out altogether, or revert to their original wild condition. We learn that the seed of the Student Parsnip is now in the English market; and the large and beautifully executed wood engravings of the progress of this new variety from the wild state to its perfected form, in the last number of the *Practical Farmer's Chronicle*, both illustrate and verify the preceding remarks.

### Pomological Gossip.

**NEW SEEDLING PEAR.**—We have been presented by Mr. J. R. Richardson, of Dorchester, with specimens of a seedling pear produced by him. In nearly all outward appearances it is a near approach to the Bartlett, being quite as large. But in quality it far surpasses it, being at the same time a month later, a season when we need more large showy pears. When well known it will take its place among our very finest pears.

**CHASSELAS VIBERT GRAPE.**—Mr. Rivers speaks highly of this grape. It obtained the 1st prize at the Crystal Palace show, May 18th, last. The judges did recognize its proper name, but awarded the prize to it as a sweet-water grape. Its berries are very large, and of a pale amber color; flavor excellent. This variety of the sweetwater grape was raised by the late M. Vibert, of Angers, some ten or more years since, and no new variety of this class is of greater excellence. Its foliage is deeply incised, very hairy on its under surface, and thick and substantial, so as to be very striking. Chasselas Duhamal is its twin brother, and was raised from the same batch of seeds. It differs but little from the Chasselas Vibert and is equally good.

**KEENS' SEEDLING STRAWBERRY.**—In our late article on strawberries, we stated that this variety was still one of the most popular sorts in England. In this we are corroborated by an English writer, who, in speaking of the principal varieties of strawberries, says: "Take Keens' Seedling for all points, it will be a long time before it is superseded by any kind at present before the English public. I have had enormous crops of these, and the flavor, though not A 1, is not surpassed by many kinds." He also remarks that he knows "it is the opinion of a good practical man, that, for forcing, no strawberries are equal to Keen's Seedling, Oscar, and Sir Harry, the first being the best."

**BRITISH QUEEN PEAR.**—This is the name given to a new seedling pear, raised by Mr. Ingram, of the Royal Gardens, Frogmore. It is supposed to have been obtained from the

Marie Louise. Specimens of the fruit were exhibited before the Royal Horticultural Society, October 8, and were awarded a first-class certificate. The fruit was above the middle size, pear-shaped, of a warm red color next the sun, and possessing a sweet juicy flesh. When better known it is said it cannot fail to be a favorite.

**VESSIER'S PEACH.**—A new French variety, fruited by Mr. Rivers in the orchard house. The specimens, from pot culture, measured  $10\frac{3}{4}$  inches in circumference, and were rich and melting beyond any late peach he had ever tasted.

**EARLY VICTORIA PEACH.**—This is the same variety that was recently noticed in our pages as River's Earliest. Mr. Rivers recently exhibited the fruit before the Royal Horticultural Society, with the request that it should be called Early Victoria, which name was adopted. Mr. Rivers' account of it is as follows:—I send you four fruits of a seedling peach which I have this moment gathered from the parent tree, raised from a stone of the early York in 1854. It has hitherto proved the earliest of all, except the Red Nutmeg, which it usually succeeds. This season it commenced to ripen on the 5th September, or a week earlier than its parent, the Early York, and this has for four years, (namely, from 1858, when it first gave fruit, to the present time,) been its tendency, with the exception of 1858, when in common with very young seedling peach trees (as I find from experience) it ripened its fruit very early, and quite ten days before its parent. It has large flowers, serrated leaves, and a habit robust and vigorous in the extreme; being, with the Early York, the only sort that was not killed last winter in the open quarter where the frost was most severe (from 4 deg. to 6 deg. below zero.) If thought worthy of a name, I propose the Early Victoria. The fruit is about medium size, pale yellow on the shaded side, and dark dull maroon on the side next the sun. The flavor was most delicious, and the fruit was highly approved by the committee as a variety for orchard house cultivation, but they suspended judgment on it as an out door variety, until it had been grown against a wall in the open air. It was superior to the Early York or Early Ann, which accompanied it.—[*Magazine of Horticulture*.]

### Raising Figs at the North.

A correspondent of the *Horticulturist*, writing from New Jersey, says:

How few there are in this latitude who have ever eaten figs, ripe and fresh from the tree! Or if, perchance, they have tasted a single specimen raised by dint of great care in a pot or tub, can scarcely credit the fact that figs may be grown, even in this northern latitude, not as

exotics under glass, but as an out-door fruit; and gathered, not as single specimens, but in generous abundance and luscious sweetness.—Yet the fact is nevertheless so, and, under favourable circumstances, two crops may be realized in a single season.

The flavour of this fruit is not generally esteemed by those to whom it is a new sensation. The taste must be cultivated, and then it becomes as fascinating as the tomato or olive.

As to the culture of the fig, there is nothing difficult. The chief requisite is to protect the tree against the severity of winter; and this is done in precisely the same manner as the tender varieties of the raspberry, viz: by covering with earth. We have seen a protection of straw resorted to, but have never known it successful in this latitude. The best method of protection is to dig about the tree in the fall, deferring the act as long as the ground remains unfrozen, and then undermining and throwing the tree, so that all the branches and canes lie upon the ground; and then to shovel upon them soil enough to thoroughly bury them beyond the reach of the frost, taking care to so leave the ground that all excess of water will readily drain off.

There is a decided advantage achieved in this process in the way of root pruning, which prevents the plant developing too much into a tree shape, and thereby rendering it, as years increase, more difficult of being protected. The uncovering should be delayed as long in the spring as possible—at any rate until the long cold storms of early May are passed, say until about the 12th of May. Then, if nothing untoward happens, you may look for a summer and autumn crop.

### Trees for Winter.

No class of plants are more useful and none made worse use of than evergreens. For shelter there is nothing like the Norway Spruce, yet we see many gardens and houses exposed to the northern blasts without an evergreen or tree or shrub to break the force of the fierce winter winds. Other gardens are nearly filled with evergreens, and this gives them a dark and gloomy appearance. For a screen, of course, the trees must be planted close in rows, but on the lawn, for beauty, here and there a fine specimen intermixed with other trees is all that is required. Trees with bright berries, like the Mountain Ash and Euonymus are very desirable, and give to the winter garden a bright and lively look. A correspondent thinks that evergreens, and especially evergreen shrubs, are neglected in this country, and writes us to urge our readers to give more attention to this beautiful class. It is true that there is no country where the evergreens are more needed than our own. Without them, how cheerless and desolate our gardens appear full five months of the year. Our attempts to introduce new evergreens, however, have not always been crowned with success, as

many things of which we had strong hopes have proved too tender for our severe climate. Then our most beautiful native evergreen shrubs, such as the Holly, the Rhododendron, and the Kalmia, are difficult to remove, and do not thrive well with common treatment and in an ordinary soil. They are not generally propagated or planted, and deserve far more attention from both nurserymen and amateurs than they have received. We have, however, many beautiful evergreen trees, that will grow as easily as a Poplar, and are hardy enough for any climate between this and the Polar Sea.—*Rural New Yorker*.

TAKING UP FRUIT TREES.—As a rule, all nursery stock should be taken up with a fork in preference to the spade; in fact we would do all we could to banish the spade from this branch of the nursery business altogether, had we the power; but at any rate, where the preservation of every root is indispensable to success, as is the case with our present subject (fruit trees), nothing but the steel fork should be employed in lifting the trees. When out of the ground, if they have far to travel, wrap the roots in some damp material, or puddle them, to prevent them becoming dry before they are replanted.—*The Florist and Fruitist*.

### Concord vs. Delaware Grapes.

It has been the source of the highest gratification to hear in every quarter the praise of the Concord grape. While at one time, few would allow it any merit, now none would risk their pomological knowledge to deny its excellence. It has indeed proved more than we claimed for it,—the universal grape for the million. It would be idle to attempt to claim for it—which was never done—a superiority in flavour to the Delaware or Diana; but as the Bartlett pear is the pear, while the Belle Lucrative is scarcely recognized, so the Concord, at present is the grape: just as long as the Black Hamburgh will be preferred to the Sweetwater, the Concord will be preferred to the Delaware.

The past year has ripened the Concord in the highest perfection. Its real excellence just begins to be appreciated. The vines have acquired age, their rampant growth has been checked, and now their fruit-bearing qualities appear. It has improved under the same circumstances that have improved others it is so much in its favour. Its hardiness saved it from destruction last winter, when the Diana and Isabella were killed to the ground; its freedom from mildew is one of its great merits, and the certainty of a crop in all seasons must place this first among our hardy grapes.

The Delaware, after fighting its way for nearly ten years, is gaining in the estimation of cultivators. Delicious as the fruit is admitted to be, and hardy as the vines are, the berries lack size

and appearance. It is a little too small, while its colour does not make that show that the dark grapes do, with their rich bloom. The vines, too, want vigour and robustness. Young vines do not take hold of the ground readily; the foliage mildews slightly, and the tender wood does not cover the trellis quick enough. But to make up for these defects, it is hardy, productive, bears young, and is as early as the Concord. In its culture it needs generous treatment, a good soil, and plenty of manure. This season it has been unusually fine.—*Hovey's Magazine*.

## The Dairy.

### Kindness to Milk Cows.

Attention, dairymen! Read! reflect! and practice! We find the following in *Wilkes' Spirit of the Times*.

One of the greatest errors in overcoming cows that are unquiet while being milked, is to whip, beat, kick, and bawl at them. This is generally done, and the cow becomes afraid and instead of becoming better grows worse. Milk cows cannot be whipped or terrified into standing quietly, gently, and patiently during milking. They dislike to be milked, for they know that loud words and hard blows always attend the operation. They dread to see the milker as the little urchin dreads to see the birchen rod in the hand of an angry pedagogue when he expects to have it applied to his back. A cow, kindly and properly treated, is pleased to see the milker, gladly awaits his or her approach, and submits with pleasure to the operation of being milked. Every one having experience with cows knows this to be true.

But the cow is opposed to a change of milkers; she soon becomes attached to one person who performs the operation, and does not willingly and freely give down her milk to another person; therefore, have one milker to certain cows, and bear in mind, if you change milkers, it is at the expense of a loss of milk and of injury to the cow. All animals appreciate kind treatment and resent abuse. See that those who milk them can control themselves, govern their passions, speak low and kindly under almost any provocation, and soon the cows will learn that they are not going to be abused, and will submit to the operation. Milking should be performed at regular hours, not varying fifteen minutes one day from the other. No talking or laughing should be permitted."

### Health of Cows.

Good health in domestic animals is always a matter of primary importance. As bad health in parents transmits a tendency to disease in the offspring, it is important that every kind of animal we desire to continue on our farms should be kept vigorous and healthy.

As domestic animals are a source of human food, it is a matter of great importance to preserve them in a healthy condition. Diseased meat carries its qualities into the stomach of the consumers. It is a serious objection which vegetarians urge against the use of animal food, that the bad treatment they receive renders them unhealthy.

As an unhealthy animal cannot consume food to as good advantage as a well one, it is again economical to avoid disease.

Each of these circumstances is sufficient reason for guarding with scrupulous care the health of the animals we feed: but when we derive milk from animals, it is doubly important that they be kept free from every objectionable taint. A sickly cow not only yields a diminished profit, but she yields sickly milk, and sickly in a higher degree than her flesh.

If a cow eats anything that has a strong or disagreeable odor it appears in her milk.

If she eats anything medical, it comes out in her milk.

If she is feverish, her milk shows it.

If she has sores about her, pus may be found in her milk.

If she is fed upon decayed or diseased food, her milk, since it has been derived from her food, will be imperfect. It is as impossible to make good milk from bad food, as to make a good building from rotten timber.

If there is anything wrong about her it will appear in her milk, as that is an effective source of casting filth from her organism.—*Hallowell Gazette*.

### Poor Milkers Dry-Up Cows.

The great importance of having cows properly milked is very forcibly illustrated by the facts stated in the following article, copied from the *Boston Cultivator*:

When I first commenced farming, I milked all my cows with my own hands; and the result was that no one in the town could boast of having made more butter, according to the number of cows than me. I well remember of having a very noble cow for milk, which would fill a twelve quart pail twice a day; and that a friend while visiting us was anxious to milk her. As I was well aware of the bad results of permitting a poor milker to milk cows that are accustomed to be milked by one faithful, regular hand, I *unwillingly consented* that he might milk her. The result was that he obtained about one-quarter less milk, than she was accustomed to give; and although I tried faithfully to draw more milk after he had finished milking, my efforts were in vain; and it was several days before I could obtain from her the amount which she had been accustomed to give.

My manner of milking was to milk as fast as possible, until a cow was milked entirely clean. I was obliged at one time, to stop milking for

only a few minutes, and I found that the cow had drawn up her milk, and I could not get it that evening.

His manner of milking was very slow and easy; and after having been milking her as long as I was accustomed to be in milking her, she withheld the remainder, and nothing that I have ever heard of, could induce her to let it down again. This taught me the importance of employing one steady regular hand at milking.

In the seasons of 1858 and 1859, my wife complained very much, when I did not superintend the milking, that we did not get near as much milk as when I was there to attend to it. Of course I could not be always there, at milking times. Then the milking would devolve on a young man in my employ who *could* milk as well and as quickly as myself, when he had a mind to do it. But as he had inherited almost every characteristic of the human race, but the faculty of *pleasing*, or of trying to please, or of making himself agreeable, even in the society of cows, when I was not there, for the slightest offence he would fall out with the cows, and beat them, and have them all in commotion. Then of course, they would not give down their milk; for a cow has complete control of it, and she will not give it to a being that she hates. All that could be said to him about being gentle with them, and milking fast while he did milk, and keeping his finger nails cut short, &c., had no more good influences than this communication will have on hundreds of other boys in their boyhood, who think that they will make cows and everything else obey their commands.

In the spring of 1859, my wife insisted that I should do the milking. I attended to it as long as was expedient, and then told this young man that he must attend to the milking, and try to do it right and to have no difficulty with the cows. Well, in less than two days, my wife said, "What is the matter with the cows, that we get only about half as much milk as usual?"

The truth on the subject is, cows know much more than some persons think they do; and they will not love a milker who has nothing lovely about him, and who will not treat them kindly; and they will give him as little of their milk as possible.

S. E. Todd.

## The Poultry Yard.

### Fattening Turkeys.

A writer in the *Germanstown Telegraph* furnishes that journal with the following statement:—Much has been published of late in our agricultural journals in relation to the alimentary properties of charcoal. It has been repeatedly asserted that domestic fowls may be fattened on it without any other food, and this, too, in a shorter time than on most nutritive grains. I made an experiment, and

must say that the result surprised me, as I had always been rather skeptical. Four turkeys were confined in a pen, and fed on meal, boiled potatoes and oats. Four others of the same broods were also at the same time confined in another pen, and fed daily upon the same articles, but with one pint of finely pulverised charcoal mixed with their meal and potatoes. They also had a plentiful supply of broken charcoal in their pen. The eight were killed on the same day, when there was a difference of one and a half pounds each in favor of the fowls which had been supplied with the charcoal, they being much the fattest, and the meat greatly superior in point of tenderness and flavor.

### Cramming Poultry.

The unnatural practice of fattening poultry by cramming is very common in France, and is described as follows: The fowls are closely confined in dark pens, where they cannot move, and get but little air. Aided by the light of a lamp, the poultryman takes three fowls at once, ties them altogether by the feet, and resting them on his knees, forces paste pellets down their throats every twenty-four hours. The finer specimens of poulardes [hens] attain a weight of upwards of 8 lbs., the cocks, 13 lbs.; and these weights are sometimes exceeded. Another mode of artificial feeding termed *entonnage*, is by causing the fowls to swallow, by means of a funnel inserted into the mouth, farinaceous substances in a liquid state. In some instances "vermineries" are established in France for the purpose of breeding maggots from putrid flesh to feed poultry on. It might not be wise for epicures to inquire too particularly into the origin of some of their favorite viands.

### Impaction of the Crop in Fowls.

Our domestic fowls are very liable to an enormous distension of the crop by food which, in the absence of secretion, and from the quantity accumulated, becomes hard and incapable of being moved from the distended cavity. The fowl lingers on without appetite, and manifesting great dulness, torpor, and progressive emaciation. Death soon puts an end to the case, and then alone, in the majority of instances, the enormous crop indicates the nature of the fatal malady.

*Treatment*—In mild cases, this consists in pouring tepid water in the gullet, and manipulating the crop so as to soften its contents and press them back through the mouth or onwards into the stomach. In severe cases, no hesitation should be experienced in making a bold incision, evacuating the crop, and

drawing the lips of the wound together by silver wire suture. The fowl must then be fed for a few days on materials which do not lodge in the crop, in order to be prepared for the action of the gizzard, and well broken down meat with sloppy bread and milk, are the best forms of food for it.—*Prof. Gumgee.*

## The Apiary.

### Wintering Bees.

In countries where bees are prevented by the cold of winter from flying out at least for two months, it is best to transfer them to a particular standing-place. In making this change the fly-holes must be stopped, but they must be opened again after the bees are put up in their winter quarters. This removal not only saves food and affords protection from the cold, but the risk of the bees being ruined and the hives stolen is thus also avoided; as in winter they are prevented by torpidity from defending themselves, entire bee-stands might in this season be destroyed. It is hardly possible to provide bee-houses sufficiently with locks; at all events, it is expensive. In transferring the bees to their winter quarters, the following rules should be observed:—

1. The transfer should not take place until the frost has set in.

2. The winter quarters should be absolutely dark, else the bees will fly from their hive without being able to find their way back.

3. A dry cellar should be chosen, or rooms with covered windows, which allow neither the warmth of a stove, nor evaporation from a stable nor from cattle.

The hives may also be placed in barns among hay or straw. If warm weather sets in after their transfer, the holes of the cellar, &c., may be opened during the following night for the purpose of cooling the stand, for it is always better to keep their standing place a few degrees below than above the freezing point; but no particular ventilation is required. There are many villages in Germany having a common subterranean place into which hives are transferred, watching them and looking after them from time to time. In such cases the fly-holes must be made more narrow, so as to protect the bees from mice. To bury them in the earth, as above described, without admitting air, forms likewise good winter quarters as the bees require still less food. [Wm. Buckisch, Patent-Office Report for 1860.]

PLANTING WHOLE POTATOES.—A correspondent of the *Mark Lane Express* says he did not see a field of defectile potatoes in Germany last season, and attributes it to the practice of planting small potatoes whole.

## Miscellaneous.

### Habits of Beavers.

The habits and habitations of beavers furnish many interesting lessons for study to the woodmen and hunters, whether scientific naturalists or not. In our boyhood the principal sources of information respecting them were the old dams and traces of dams that were found on every little brook where we fished or hunted cowslips for greens. These beaver dams consisted of ridges of earth from four to five feet above the common level of the "beaver meadow" flat, running each way from the brook to rising land. We would find great numbers of these dams when it would be hard to understand how they could ever make ponds of sufficient depth for the beavers' use. But the brooks in the primeval forest, before the incursions of civilization, afforded more water than in modern times, and in many instances the marshy pools which the beavers' habits require, by natural process have grown up and filled up to solid land. As in the older part of the country no new works were found, it was generally understood that the beavers left and moved off whenever civilized settlements grew up near them, and we have been surprised to find in this region the evidence of so many working beavers. On the different tributaries of the St. John river, running out of this State, there are some hundreds of them caught every year, and they do not seem to diminish. Hunting parties, whether of white men or Indians, consisting usually of two or three men, get from ten to twenty beavers in a winter's hunt. Lumbering operations have a tendency to drive them to the small brooks and head sources of the rivers, when found on "driving streams" their dams have been torn away; but they do not seem particularly shy of men or settlements unless their dams or houses are destroyed. Four or five years ago, it is said, a company of them built dams and houses in the town of Ashland, only two miles from the village, or corner, as it is called, and staid two years, when a part were caught, and the rest driven away, by the hunters.

There are two kinds of them, differing only in habits. For some reason, now and then one of them usually wanders alone, and has only a hole in the bank of the river to live in, while they generally live in pairs or families, building houses and providing stores in companies—hence the terms "family" or "working beavers." The supposition is, that the bank beavers are such as have for some reason come short of a mate, or for idleness have been driven from the ponds and houses. They are the same animals every way, only exiles. The law of industry among the working beavers is well attested by hunters. Their dams or houses are built anew or remodelled every fall, in a way to suit the height

the water during the succeeding winter or spring. The object of the dam seems to be to regulate the height of water at their houses, where they have two or three berths at different heights, where they sleep high and dry, but with their tails in the water, thus being warned of any change in the rise and fall of water. Some houses stand six feet at least above the surface of the meadow, covered with mud, in the form of a round coal pit, but intersected with sticks of wood, so as to be strong, and the weight of three or four men makes no impression upon it.

A "full family," as hunters call them, consists of the parental pair and the males of the next generation, with their mates. When the tribe gets larger than this they colonize. Some time in the fall all single ones of both sexes congregate from considerable distances at the deepest lake in the vicinity, where they choose their mates; how ceremonious the nuptials we cannot say; they all go home, the female following her mate, and all go to work, first putting the house and dam in order for winter, then laying in their stock of wood, the bark of which is their winter food. They go up stream some three miles for their wood, and run it down to their houses, and then in some mysterious way make it lie in a pile at the bottom of the pond, outside of the house, where they may take it in any time in the winter for use. It is said that no human hands can disturb that wood with its rising and remaining afloat till the beaver has the handling of it again. But we do not feel quite sure what is fact and is conjecture respecting the beaver, whose works are so much in the night, and deep under water. The fall of the year is a busy time with them, and it interesting to see the new dams in process of building, as we sometimes find them across large boating streams, and not unfrequently boatmen and river drivers tear away their dams and get a good head of water for their use. They usually build at the outlet of natural ponds, and sometimes they flow large lakes and pieces of dead water, but are always moving and reconstructing. How they keep their teeth in order for so much eating, when the best steel would wear out, is a mystery. They cut logs sometimes a foot through, and every stroke of the tooth tells toward the job, and never does a tooth get dull as we can see. Two winters ago, near Ashland, some lumbermen encamped near one of their ponds. One afternoon they felled a tree across the lumber road, and before morning it was handsomely cut up and piled out of the road.

—*Aroostook (Maine) Pioneer.*

**THE LARK AND HER YOUNG ONES.**—A lark, who had a brood of young ones in a field of corn which was almost ripe, was very much concerned lest the reapers should come before the little ones were able to fly: so, whenever she went abroad to seek food, she told the young larks to be sure and listen to all the news. One day, while she was absent, the master of the field, and

his son came to look at the crop. "This corn," said the father, "is quite ready for the sickle; to-morrow go and ask our neighbours and friends to come and help us to reap it." When the old lark came home, the young ones, in a great fright, told her what they had heard, and begged her to remove them at once. The mother said "There is no cause for fear; for if he trust to his neighbours and friends for help, I am certain that the corn will not be reaped to-morrow." The next day the lark went abroad as usual, giving them the same directions as before. The farmer came to the field, and waited hour after hour for the expected help; but, finding the day passing away and the corn getting more ripe, and no one coming to his assistance, he said, "We must not, I find, depend upon our neighbours; so to-morrow go and ask our relations—our cousins and uncles—to come and help us." In still greater fear, the young larks told their mother what they had heard. "There is no occasion to hurry away yet," coolly answered the lark, "for I know that their cousins and uncles have work enough of their own." The lark again went abroad, and the farmer coming to the field, found his corn spoiling through over-ripeness. He waited for some time to see whether his relations appeared to help him; but finding that they did not come any more than his neighbours, he said, "My son, let us lose no more time; to-morrow we will cut down the corn ourselves." When this was reported to the old lark, she said, "Now, my young ones, the sooner we get away the better; for when a man determines to do his own work, you may be sure that he is in earnest." *What the lark said is quite true.*

**PRESERVATION OF STONE.**—At a late meeting of the Institute of British Architects, Sir Henry Rawlinson stated that the old Assyrians were acquainted with modes of preserving stone from decay. In Mesopotamia he had seen a huge rock the whole face of which was covered with inscriptions, coated over with some kind of varnish which he supposed was the silicate of lime. These inscriptions were executed 900 years before Christ were in a perfect state of preservation, and the varnish was harder than the limestone rock beneath it.

**"PLOWING A MAN IN."**—The Herts (England) Advertiser gives the following interesting example of the carrying out of an old English custom—a custom which we had referred to as still not unfrequently acted upon, in Scotland as well as England: The development of one of these good old friendly country customs took place on Wednesday, Nov. 6, in consequence of the recent entry or occupation of Mr. John Ransome, on Weathamsted Bury farm, which extends 450 acres. Although Mr. Ransome only came into this part of this country a few years since, a perfect stranger, he has, by his practical intelligence, perseverance, urbanity, and honorable conduct, gained the esteem and regard of

so many friends, that they were determined to show and testify their sense of the man by sending him their teams, which poured on to the farm from far and near at early dawn on the Wednesday morning in such numbers that it required Mr. Ransome to exercise a great deal of tact and management to place the right plows in the right places. To the uninitiated it may be proper to say it is an old and established custom in this country for the neighbors to send a plow and a team of horses to assist a tenant upon entering upon a new occupation of a farm, and on this occasion the muster was unprecedented; one hundred and forty-three plows, drawn (in round numbers) by 500 excellent horses, whose value might be set down at £15,000 (say \$75,000,) averaging each at £30, might be seen turning up mother earth to the extent of upwards of 130 acres, the plowing generally being unusually good. An excellent luncheon was provided at the farm house, and many gentlemen availed themselves of the offer of Mr. Ransome's kind hospitality, and who did not forget to drink the health and happiness of Mr. Ransome and his amiable lady.

**HOW SALT AND SALTPETRE ACT ON MEAT**—The properties and action of articles in frequent and common use, should be well understood, especially when those articles are used in the preparation of human food. Hence the following remarks from the *Farmer and Gardener* will be interesting and instructive to many of our readers: "The matter in which salt operates in its preservative functions is obvious. Salt, by its strong affinity, in the first place, extracts the juices from the substance of meat in sufficient quantity to form a saturated solution with the water contained in the juice, and the meat then absorbs the saturated brine in the place of the juice extracted by the salt in the first place. This matter incapable of putrefaction takes the place of that portion of the meat which is most perishable. Such, however, is not the only office of salt as a means of preserving the meat; it also acts by its astringency in contracting the fibres of the muscles, and so excludes the action of the air on the interior of the substance of the meat. The last mentioned operation of salt as an antiseptic is evinced by the diminution of the volume of meat to which it is applied.

The astringent action of saltpetre on meat is much greater than that of salt, and thereby renders the meat to which it is applied very hard; but in small quantities it considerably assists the antiseptic action of the salt, and it also prevents the destruction of the florid (or red) color of the meat by the application of salt. From the foregoing statement of the mode of operation of salt and saltpetre on meat, it will be perceived that the application of these matters deteriorates, in a considerable degree, the nutritive, and to some extent, the wholesome qualities of the meat; and therefore in their use, the quantity applied should be as small as possible consistent with the perfect preservation of the meat."

**INFLUENCE OF TREES UPON CLIMATE.**—Jochim Frederic Sahouw, Professor of Botany at Copenhagen, speaks as follows of the influence of forests upon the atmosphere:—"We find the most evident signs of it in the torrid zone. The forests increase the rain and moisture, and produce springs and running streams. Tracts destitute of woods become very strongly heated, the air above them ascends perpendicularly, and thus prevents the clouds from sinking, and the constant winds (trade winds or monsoons), where they can blow uninterruptedly over large surfaces, do not allow the transition of vapors into the form of drops. In the forests, on the contrary, the clothed soil does not become so heated, and, besides, the evaporation from the trees favors cooling: therefore, when the currents of air loaded with vapors reach the forests, they meet with that which condenses them and change into rain. Since, moreover, evaporation of the earth goes on more slowly beneath the trees, and since these also evaporate very copiously in a hot climate, the atmosphere in those forests has a high degree of humidity, this great humidity at the same time producing many springs and streams."

**SUDDEN COLD WEATHER.**—A writer in the *North American Review*, in discussing the subject of climatology, refers to the sudden "cold snaps" of our northern winters, and expresses the opinion that they are occasioned by the descent of the cold atmosphere above, or its transference from above. In illustration of this, it is stated that every few years, a storm like the one described below occurs, generally with less severity.—The weather of the last week may afford further illustration of this point and makes this matter of greater interest at the present time. In January, 1810, occurred the *cold Friday*, as it was for years called. The weather had been fair and pleasant, and on Thursday the temperature was uncommonly high, rising even to 60 degs., and the wind from the south. Toward sunset the appearance of a coming storm was obvious. It burst upon the western part of Massachusetts about sunset, or a little later, in a snow-squall from the north of west, of terrific violence, with the power and fury of a tornado. Desolation marked its course. The cold increased with great rapidity; at midnight the thermometer was at zero, and the next morning at 20 deg. below, in some places colder. Friday was insufferably cold; the wind was strong; the thermometer did not rise to zero over much of New England and New York, and in Canada it was still lower. The storm passed over a large portion of our country, and everywhere with a great degree of cold.

**WE SLEEP TOO LITTLE**—But if night, and not day, is the time to sleep, then it may be said that the general principle prevails that the amount of sleep should be regulated by the dividing line between light and darkness; and that

this view may be accepted as the correct one, is determined from analogy;—it being true that animals accept any act upon it in the temperate latitudes, which are supposed to be the most favorable for the development of the human organism in its highest proportions. Take the year together, day and night are about equal; and were mankind within these latitudes to live according to the laws of life and health in other directions, they would sleep while darkness is on the face of the earth, and be active only during the time in which light was abundant. As a habit and fashion with our people, we sleep too little. It is admitted by all those who are competent to speak on the subject, that the people of the United States, from day to day, not only do not get sufficient sleep, but they do not get sufficient rest. By the preponderance of the nervous over the vital temperament, they need all the recuperating benefits which sleep can offer each night as it passes. A far better rule would be at least to get eight hours' sleep, and including sleep, ten hours of incumbent rest. It is a sad mistake that some make, who suppose themselves qualified to speak on the subject, in affirming that persons of a highly-wrought, nervous temperament, need—as compared with those of a more lymphatic, or stolid organization—less sleep. The truth is, that where power is expended with great rapidity, by a constitutional law, it is regathered slowly;—the reaction after a while demanding much more time for the gathering up of new force, than the direct effort demands in expending that force. Thus a man of the nervous temperament, after he has established a habit of overdoing, recovers from the effect of such overaction more slowly than a man of different temperament would, if the balance between his power to do and his power to rest, is destroyed. As between the nervous and the lymphatic temperaments, therefore, where excess of work is demanded, it will always be seen that at the close of the day's labour, whether it has been of muscle or thought, the man of nervous temperament, who is tired, finds it difficult to fall to sleep, sleeps perturbedly, wakes up excitedly, and is more apt than otherwise to resort to stimulants to place himself in conditions of pleasurable activity. While the man of lymphatic temperament, when tired, falls asleep, sleeps soundly and uninterruptedly, and wakes up in the morning a new man. The facts are against the theory that nervous temperaments recuperate quickly from the fatigues to which their possessors are subjected. Three-fourths of our drunkards are from the ranks of the men of nervous temperament. Almost all opium-eaters in our country—and their name is Legion—are persons of the nervous or nervous-sanguine temperaments. Almost all the men in the country who become the victims of narcotic drug-medication, are of the nervous or nervous-sanguine temperaments. That the very general habit of dependence upon stimulants, or stimulo-narcotics,

is almost entirely confined to persons of the nervous temperament's, shows that the taxations to which they subject themselves, are not readily reacted from; and that under their methods of living, they find it difficult to depend upon the natural force to make good their losses within the time they allot for that purpose. The rule therefore, should be the other way from that which it is supposed to be—namely, that persons of highly wrought nervous organization need but little sleep. It should be the habit of such persons to sleep largely, and to insist upon such freedom from exercise, both of body and mind, and such external conditions of repose, as gradually to bring the brain to acknowledge such relations to the general structure, as will enable its various organs to become so refreshed, that they may, when duty is resumed, perform it with accustomed yet healthy vigor.—*Dr. J. C. Jackson*

**EARLY RISING.**—In New York there has been formed a Young Men's Early Rising Association, all the members of which are obliged to be up at a certain hour. It originated with about half-a-dozen men, who, having kept up this habit for some years, were surprised at its beneficial effects, and at the marked success in life of their associates.

**THE VICTORIA FALLS IN AFRICA.**—Some very interesting news has been received from Dr. Livingstone. His description of the Victoria Falls is worth quoting. He says: "After a second visit, I am inclined to believe that the Victoria Falls are the most wonderful in the world. It is the only grand sight the gentle Africans have to show, I tried to get them taken by an artist, but, to my regret, I failed. The breadth is not one thousand yards, as I conjectured, but between one statute and one geographical mile—we say eighteen hundred and sixty yards, by way of assisting the memory, but it is a little more. Then the river of this breadth leaps down, not one hundred feet, but three hundred and ten feet, *i. e.*, if my memory deceives me not, double the depth of Niagara. It is a few feet more, as the weight attached to our line rested on a slope near the bottom. Then the fissure into which it falls, though, when seen from Garden Island, looks like the letter L, is prolonged in the most remarkable zig-zag manner. The promontory formed by the zig-zag enabled me to see the falls on the east side as well as from the island, and being level, and of the same altitude as the bed of the river above the falls, you can walk along and see the river some three hundred feet before you, and on both sides of you, jammed in a space of twenty or thirty yards. The base of one promontory is only one hundred and thirty paces from a dry fissure, and the base of another is only four hundred paces broad, measuring from the fall fissure to it. Nothing but several oil paintings could give an idea of the wonderful scene; and it was solely against my will that I had to forego this, which would have

been a feather in the cap of our expedition, and a good thing for our artist as well. The river was now very low—never saw it so dry; indeed, people could wade from the north bank to my Garden island. This enabled me to see the whole thing plainly, but even now there were 800 feet of waterfall. The columns of vapour were fewer—only two good ones, I think. I could not measure their height—probably over 200 feet. The lips of the fissure at Garden Island, when measured by sextants, were eighty feet; but we could not throw a stone across, so it may be more. Come when you may, you will not be disappointed by the falls of Victoria. We bought canoes at Sinamanes, and dropped down the stream to below Chicona. Kersale has no impediment, but a basaltic dyke a little below makes it a dangerous rapid for canoes. There is another dangerous rapid for canoes at Mburuma's, but a boat would go through easily. The canoes were but six inches above the water, and easily filled."

**VENTILATION OF THE APPLE BARREL.**—By this we mean the boring of holes in the head of staves of the barrels that will allow the escape of the moisture that is constantly passing off from the newly gathered fruit. We hazard nothing in the statement that one half the fruit sent to this market this season, so far, has been materially injured from this cause. The effect of confined vapor upon the apple is not at once apparent. The fruit appears uncommonly bright on the first opening—but as the surface dries off the apple begins to grow dull looking, and if a light skinned apple, in day or two will present the appearance of half baked fruit. But this steaming from confinement, not only injures the sale of fruit, but to the great disappointment of the consumer, his fruit does not keep as he supposed it would, and as the variety of apple he purchased led him to suppose it would. Premature decay is soon to follow as a consequence of this want of ventilation.—*Chicago Fruit Dealer.*

**HOW TO HANDLE FIREARMS SAFELY.**—An old sport-man gives the following advice in reference to the safe handling of percussion guns:—When the gun is charged, never allow the lock to be in any other state than at half cock, except at the moment before firing. The reason why this rule should be adopted and religiously observed are briefly these: the lock is so constructed that when at half cock (provided it is good for anything, and no other should ever be used) it cannot be moved from that point toward the cap to explode it in any possible way. You may strike it violently, and it will not yield until the lock itself breaks in pieces. If, by any accident it is moved in the opposite direction, it must go back until it is fully cocked, and must remain there until the trigger is touched. If it does not go back to that point, it cannot possibly, in returning, pass the point of its first position—that of half cock—unless the trigger is touched at the moment, which would seldom if ever happen.

**AN EGG IN A BOTTLE.**—To accomplish this seemingly incredible act requires the following preparation. You must take an egg and soak it in vinegar, and in process of time its shell will become quite soft, so that it may be extended lengthwise without breaking; then insert it into the neck of a small white bottle, and upon pouring cold water upon it, it will assume its former figure and hardness. This is really a curiosity, and baffles those who are not in the secret to find out how it is accomplished.

**WHAT INFLUENCES OUR CLIMATE.**—I cannot omit directing the reader's attention to the influence the far-distant barrier of Central America has upon the climate of great Britain. Supposing you narrow belt of land to be suddenly whelmed by the ocean; then, instead of circuitously winding round the Gulf of Mexico, the heated waters of the equatorial current would naturally flow into the Pacific, and the Gulf stream no longer exist. We should not only lose the benefit of its warm current, but cold polar streams, descending further to the south, would take its place, and be ultimately driven by the westerly winds against our coasts. Our climate would then resemble that of Newfoundland, and our ports be blocked up during many months by enormous masses of ice. Under these altered circumstances, England would no longer be the grand emporium of trade and industry, and would finally dwindle down from her imperial station to an insignificant dependency of some other country more favored by Nature.—*Hartwig's Sea and its Wonders.*

**TO PREVENT FLIES FROM TEAZING HORSES.**—Take two or three small handfuls of walnut leaves, upon which pour two or three quarts of soft cold water; let it infuse one night, and pour the whole next morning into a kettle, and let it boil for fifteen minutes. When cold, it will be fit for use. No more is required than to wet a sponge, and before the horse goes out of the stable, let those parts which are most irritated be smeared over with the liquor.

**BLISTERED FEET.**—A writer says:—"I had for several years two sons at school at Geneva, Switzerland. In their vacations they, in company with their tutor, made excursions through Switzerland, Italy, Germany, &c, on foot; bearing their knapsacks containing their necessary wants for a month. They were provided with a small bar of common brown soap, and before putting on their stockings turned them inside out, and rubbed the soap well into the threads of them; consequently they never became foot sore, or had blistered feet.

**THE LABOURER ON THE CONTINENT.**—The system of small farms (*la petite culture*) so generally prevalent throughout the Continent, markedly so in France and Belgium, induces a condition of things vastly different from that prevalent in this country; and hence we find that the class of

men who hire themselves out for farm labour is not in any way so important as the class with us. Farm labourers are not numerous, as large farmers requiring their services are anything but numerous themselves. Their place is taken by the body of peasant proprietors, who may be said, in general terms, to represent our agricultural labourer class. I have travelled pretty extensively on the Continent, and I confess to having formed a very favourable opinion as to the condition of the agriculturists of the lower ranks. Time will only permit me however to glance at their condition in Belgium; more especially that part of it—Flanders—where cultivation stands so deservedly high. Wages are not great; a farmer in the neighbourhood of Courtrai, who farmed about 90 acres, told me that he gave his labourers 67 centimes per day, that is about 7d. per day with an ample supply of provision—meat, bread and soup. From a franc to a franc and a quarter may be stated perhaps as the average without provisions. Nearly all the labourers have small plots of ground, which they have time to cultivate, and which they do with the most pains-taking care. That the condition of the labourer is in every way a comfortable one, even a cursory investigation will easily show. The clothing is wonderfully good, far above—especially in the linen department—that of our labourers. In the districts where the small plots of land are cultivated by the peasant proprietors pleasant signs of personal and household comfort abound everywhere. The village streets through which one passes how little of the squalid untidiness which too often greets the eye of the traveller in this country; and seldom is he offended with the sight of children bouncing about in all the Arab freedom of dirt and rags which characterises too many of the rising youths of our own villages. Nor, let me add—which possibly is one grand reason of all this comfort—do you see the drunkard staggering through the streets in the hopelessness of confirmed degradation. The cottages are small, and scantily furnished, according to our ideas of furnishing; but a scrupulous cleanliness atones for this, and adds a charm which abundance of furnished wealth without it would not give. The personal dress of both sexes gives you the idea of great comfort, although in the materials employed you have no evidence of the abundance of money. It simply tells of small funds laid out to highest economical advantage, than which nothing I conceive is more satisfactory in peasant life.—*Mr R. S. Burn before the London Farmer's Club.*

**WHAT THE CHINESE EAT.**—Rice is the staple article of food with all these Chinamen, as with the coolies and farmers, the only difference being that they have their fish and vegetables in quantity enough to be served up on separate dishes, and of much more expensive kinds than those bought by the poorer men. A choice addition consists of thin slices of pork fat, rolled up, cut

into lengths of about an inch, and until most of the grease is drawn out, leaving the rest crisp and brown, and not unpalatable. Bread is never eaten in the provinces south of Shantung, its place being entirely taken by rice; but there is a sort of dumpling made of flour, sometimes plain and sometimes with mincemeat or dried fruit in it. Small cakes are also made from rice and barley flour with seeds like carraways strewed on the top. Heavy sponge cakes made in a mould, and cakes made from bean flour, are also in request. The Chinese aristocrat never feasts (if he can help it) without roast sucking pig for one dish, and of roast pig the part he prefers is the crackling. Every reading child knows about bird's-nest soup and the Indian sea slug biche-de-mer. Eggs are baked in clay until quite hard, and eaten in slices. Deer's sinews and pig's ears are great favourites. They have also excellent soups, thickened with first-rate vermicelli. In Foo-chow-foo bacon and hams are prepared, which many pronounce to be as good as English; at all events, they are famous all over China, and are always a very acceptable present to the residents at the other ports. They have even been exported to America, though, no doubt, only as curiosities. It is said that the art of curing hams was introduced into Foo-chow by a resident English lady some twelve years ago.—*All the Year Round.*

To drive and keep rats from corn-cribs and granaries, place some gas-tar in them, and daub some in their holes, and they will leave the premises at once. The tar can be obtained at any place where gas is manufactured.

**TO REMOVE CHAFF FROM ANIMALS' EYES.**—Mr. C. E. Todd states, in the Ohio Farmer, that he had a valuable cow which became partly blinded with oat chaff, and tried the various remedies commonly prescribed, but to no effect. He then took a silk pocket-handkerchief, drew it tightly over the end of the fore-finger, and after raising the eye-lid as much as practicable, thrust the covered finger carefully into the eye. The chaff adhering to the silk was at once removed.

**NATURAL FOUNTAINS IN ICELAND.**—Two of these fountains, within a yard of each other, erupted alternately—the larger one vomiting a column ten feet high for the space of about four minutes, when it would entirely subside, and then the smaller one took up the running for about three minutes, ejecting a column of about five feet: their regularity in time and force was perfect. What gives rise to this remarkable phenomenon I will not attempt to decide, but there are reliable accounts of their regular habits for the last hundred years.—*Iceland; its Volcanoes, Geysers and Glaciers.*

**THE CONDITIONS OF LIFE.**—It is hard to know whether more to admire the variety of the form under which food is supplied to the animal creation or the simplicity of the fundamental

plan. The nutritious substances baffle calculation, and embrace the utmost diversity of kinds, adapted to every variety of climate, circumstance or habit. While the living organism, on the one hand, can build up a solid frame from liquid materials, on the other, it can pour iron through its veins, and reduce the hardest textures into blood. There is a squirrel in Africa that feeds on elephant's tusks; and the mark of his teeth is a welcome sight to the ivory-collector. The cunning creature selects—for there is scope for epicurism even in this hard fare—the tusks which are richest in animal matter, and which are therefore, the most valuable. But under what diversity of form it may be presented, food is in its essential nature always the same. To give us active bodies, it must be an active substance; that is, it must consist of elements which tend to change through the operation of their chemical affinities. To furnish food for animal life is in one aspect a simple problem, though wrought out in infinite complexity. It is to provide matter in unstable equilibrium, as it is said, or constantly tend to assume new forms, like waves raised in water by the wind. Yet it must not be utterly incapable of retaining its existing form, but should be delicately balanced, as it were, so that it will admit of being transferred and moulded in various way, unaltered, and yet will undergo change immediately when certain conditions are fulfilled. Given a substance thus composed, and there is food. For we must not limit our ideas here to that which happens to be food for us, or for the creatures likeliest to ourselves. Food is found by some creature or other in circumstances the most widely diverse. There is hardly a poison known that does not afford sustenance to some form of life. Corrosive minerals in solution afford nutriment to peculiar kinds of mold or cell plants. Even the gastric juice—the “universal solvent”—will sustain, without losing its properties, special fungus. The fable of Mithridates, who accustomed himself to eat all deadly things with impunity, is more than realized in nature. Life in its widest sense almost refuses to recognize a poison. What is death to one organism supports another. Thus many diseases—an ever-increasing number of them indeed—are found to consist in the development of parasites; a new and hostile life invading the old, and flourishing in its destruction. And some of the most virulent vegetable poisons differ but slightly in composition from perfectly wholesome substances.—*Cornhill Magazine*.

**A MICROSCOPIC AGE.**—A correspondent of *St. James' Magazine* says:—“If I were to point out what is the most striking characteristic of the present century, I do not think that I should dwell upon it as a scientific age, or as a literary age, or as a missionary age (by all which epithets it has been described), but as a microscopic age. Nothing appears to be so

wonderful as the changes which have occurred in the common doctrine of magnitudes. Little things have become great and great things have become small. As the modern science of chemistry could not spring into existence until an accurate balance was invented, so the modern science of physiology and the following theory of mortal life, as we now comprehend it, has grown out of the microscope. This is a literal fact, and it is symbolic of a much wider one,—that all modern research has become microscopic. Painting has become microscope, and gives us details of mosses and lichens, which a half century ago would be laughed at as a useless waste of time. History has become microscopic, and enlivens the descriptions of courts and senates with a minute account of carpet and cakes, dresses, dinners, and other trivialities. Poetry has become microscopic and tells us that the meanest flower that breathes can give to the bard thoughts that do lie too deep for tears.”

**A NEW USE FOR APPLES.**—A country paper says:—“We are threatened with a cider famine, not from failure of the apples, although a partial crop, but because they are likely to be applied to a more profitable purpose (so far as the growers are concerned) than in making a household beverage. It seems that the Manchester calico dyers and printers have discovered that apple juices supply a desideratum long wanted in making fast colours for their printed cottons, and numbers of them have been in Devonshire and the lower parts of Somersetshire, buying up all the apples they can get, and giving such a price for them as in the dearest years hitherto known has not been offered. We know of one farmer in Devonshire who has a large orchard, for the produce of which he never before received more than £250, and yet he has sold it this year to a Manchester man for £360. There can be no doubt that the discovery will create quite a revolution in the apple trade.

**LIGHT IN THE SEA.**—A paper on the nature of the Deep Sea Bed, by Dr. Wallich, was lately read at a meeting of the Royal Institution of Great Britain. The following passage occurred in it:—“Light, or rather the absence of it, can hardly be said to determine, in any important degree, the distribution and limitation of the lower forms of animal life. Light is not essential even in the case of some of the lower orders. A large class of creatures, both terrestrial and marine, possess no true organs of vision, although there is good reason for believing that they do possess some special sensory apparatus susceptible to the influence of light; whilst certain creatures, whose habitation is in subterranean caves or lakes, as in the Magdalena near Adelsburg, and the Great Mammoth caves in Kentucky, either possess them in so rudimentary a state, as to prove clearly that the absence or imperfect development of the sense may be compensated for by the higher development of other

senses. It is impossible at present to say to what depth light penetrates in the sea. The photographic art will, no doubt, one day solve the problem. But it is almost certain that a limit is attained, and that, moreover, long before the deep recesses gaged by the sounding machines are reached, wherethe light-giving portion of the ray cannot penetrate even in its most attenuated condition; and yet, as shall hereafter be shown, creatures have been found down in those profound and dark abysses whose coloring is as delicate and varied as if they had passed their existence under the bright influence of a summer sun."

**A REMEDY FOR SLEEPLESSNESS**—How to get sleep is to many persons a matter of great importance. Nervous persons, who are troubled with wakefulness and excitability, usually have a tendency of blood on the brain, with cold extremities. The pressure of blood on the brain keeps it in a stimulated or wakeful state, and the pulsations in the head are often painful. Let such rise and chafe the body and extremities with a brush or towel, or rub smartly with the hands, to promote circulation, and withdraw the excessive amount blood from the brain, and they will fall asleep in a few moments. A cold bath, or a sponge bath and rubbing, or a good run, or a rapid walk in the open air, or going up or down stairs a few times just before retiring, will aid in equalizing circulation and promoting sleep. These rules are simple, and easy of application in castle or cabin, mansion or cottage, and may minister to the comfort of thousands who would freely expend money for an anodyne to promote "Nature's sweet restorer, balmy sleep."

**BATHING IN THE JORDAN.**—The shore was muddy with the feet of the pilgrims, and the river so rapid that I hardly dared to get beyond the mud. I did manage to take a plunge in head-foremost, but I was forced to wade out through the dirt and slush, so that I found it difficult to make my feet and legs clean enough for my shoes and stockings; and then, moreover, the flies plagued me most unmercifully. I found that with them, bathing in Jordan has come to be much the same as baptism with us. It hardly means immersion. No doubt that they do take off their shoes and stockings, but they do not strip and go bodily into the water. —*London Review.*

**STEAM PLOWING**—I cannot conclude this notice of the steam engine without observing the changes it is destined to effect in the cultivation of the soil. It is but a short time since it was thought inapplicable to agricultural purposes from its great weight and expense. But more recent experience has proved this to be a mistake, and ready in most districts we find that it has been pressed into the service of the farm. The small motive, mounted on a frame with four

wheels, travels from village to village with its attendant, the thrashing machine, performing the operations of thrashing, winnowing and cleaning at less than one half the cost by the old and tedious process of hand labor. Its application to plowing and tilling on a large scale is, in my opinion, still in its infancy; and I doubt not that many members of this association will live to see the steam plow in operation over the whole length and breadth of the land. Much has to be done before this important change can be successfully accomplished; but, with the aid of the agriculturist preparing the land so as to meet the requirements of the steam machinery, we may reasonably look forward to a new era in the cultivation of the soil.—*Id.*

**CONSTITUTION OF THE SUN.**—Our knowledge of the physical constitution of the central body of our system seems likely, at the present time, to be much increased. The spots on the sun's disk when noticed by Galileo and his contemporaries, and enabled them to ascertain the time of its rotation and the inclination of its axis. They also correctly inferred, from their appearance, the existence of a luminous envelope, in which funnel-shaped depressions revealed a solid and dark nucleus. Just a century ago, Alexander Wilson indicated the presence of a second and less luminous envelope beneath the outer stratum, and his discovery was confirmed by Sir William Herschel, who was led to assume the presence of a double stratum of coats, the upper intensely luminous, the lower gray, and forming the penumbra of the spots. Observations during eclipses have rendered probable the supposition that a third and outermost stratum of imperfect transparency encloses concentrically the other envelopes. Still more recently, the remarkable discoveries of Kirchhoff and Bunsen require us to believe that a solid or liquid photosphere is seen through an atmosphere containing iron, sodium, lithium, and other metals in a vaporous condition.

We must still wait for the application of more perfect instruments, and especially for the careful registering of the appearances of the sun by the photoheliograph of Sir John Herschel, so ably employed by Mr. Warren de la Rue, Mr. Welsh and others, before we can expect a solution of all the problems thus suggested.—*Id.*

**THE HOUSE SPARROW.**—As Mr. Broderip was passing one day along the footway that borders the National Gallery, he saw a sparrow fly down to the neighbouring hackney carriage stand, and pick up a very long straw, with which it flew, with some labour, towards the building. The long, streaming straw attracted the attention of some of the pedestrians, who stopped and looked at the little loaded bird, who was directing its flight towards the portico of the gallery; but finding its motions watched, it turned short round and pitched with its straw on one of the window-sills, and the people then passed on. Presently it flew again towards the portico; but, the people again stopping and looking—for if one passenger stops and looks up in a great

London thoroughfare, you have in a very few moments an increasing crowd—it flew back to another window, and the second lot of gazers went their way. The little bird then started again with its straw towards one of the same pillars, and cutting round it, so as to avoid prying eyes as much as possible, bore it to the capital of one of the pillars, and disappeared, straw and all, into a snug nook made by a part of the projecting ornament, which it had chosen as the place for building its nest. "The wary bird," adds Mr. Broderip, "was not disposed to let an inquisitive public know the way to its home. On many other occasions I have observed these and other birds remain waiting about a long time with nest materials and food in their bills, when they have perceived that I was watching them; but the moment I turned my head they were off with their burden to the nest. This would not be worth mentioning, were it not so difficult to find persons who will use their eyes to some purpose."—*Cassell's Popular Natural History*.

**FARMERS' NEWS.**—One plant of the weed black mustard (*Sinapis nigra*) gives 200 flowers: and each giving six seeds, 1,200 seeds are produced. One plant of the tare (*Ervum tetraspermum*) gives sixty flowers: and each flower giving three seeds, 180 seeds are produced. The seeds of hemp retain their germinating power for three years, rape the same, buckwheat two to three, barley three, cabbage five to six, and beans and peas five to six. Sixty feet superficial should be allowed for each animal in the shed, and 240 feet in the courtyard. A beater thrashing machine can thrash out 7 qrs. 1 bushel 28 lbs. of wheat (taken after beans) per hour.

**TO STOP BLEEDING.**—Asa Kemper, Ross County, Ohio, writes to the *American Agriculturalist*, that bleeding from wound on man or beast, may be stopped by a mixture of wheat flour and common salt, in equal parts, bound on with a cloth. If the bleeding be profuse, use a large quantity, say from one to three pints. It may be left for hours, even days if necessary. In this manner he saved the life of a horse, which was bleeding from a wounded artery; the bleeding ceased in five minutes after this application. It was left on three days, when it worked loose, and was easily removed, and the wound soon healed.

**LOCALITIES OF FISH.**—The fact that fish herd together in great flocks or nations seems now to be well established. All the inhabitants of the great deep, from the mighty whale down to the minnow, live in what may be termed colonies. Thus we have the term "a school of whales." We have also the young salmon in shoals—each year's growth in separate companies, and every fish as local in its dwelling-place as men are. We know, too, that the herrings live also in nations, which arrive at maturity in vast groups at

different periods of the season. The same laws govern the crustaceæ. Persons who deal in shell fish can easily tell the different localities whence they derive their different supplies. A Scotch lobster can be readily distinguished from a Norway one, and "a native" oyster differs considerably from a "scuttle moun'b." These are all points which ought long ago to have led to a better understanding of the natural and economic history of fish. This ignorance has well nigh ruined our most valuable fisheries. We have been trading for years in the belief that the supply was inexhaustible, and are but beginning to find out that it is even possible to exhaust the sea. The German Ocean has been so long the fishing pond of Europe, that we can scarcely wonder, considering the wealth that has been drawn from its depths, that its supplies are beginning to fail us. There can be no doubt, however, that other sources of supply will be discovered; if so, we can only hope that some method will be observed in harrying the nest, in order that the supply may be made to go as far as possible.—*London Review*.

### Tobacco for Sheep Ticks.

**EDITOR OR FARMER.**—I notice in a late number of the *Farmer* an inquiry in regard to the use of tobacco for killing ticks upon lambs, of which the writer Geo. P. Morse, thinks is a sure remedy for killing both the tick and the lambs.

Now, I will give my experience in the use of tobacco on lambs: I have made it a practice for years whenever my sheep were ticky, to dip the lambs in tobacco juice. I take about four pounds of what the merchants term poor tobacco. Place in a caldron kettle; boil until you have the strength, then reduce it nearly one half with water that will be a sufficient quantity for one hundred lambs. This will kill the ticks sure and leave the animal healthy and vigorous; at least such has been the case with my flock. My mode is this: After shearing let all my sheep go in one flock for four or five weeks; the tick will all leave the old sheep and go on the lambs. Then prepare as above and dip your lambs.—By so doing, you will clear your flock of an enemy which has been very destructive in many fine flocks of sheep. Try and See.

M L. RAY.

Concord, April, 1861.—*Michigan Farmer*.

**THE STUDY OF SCIENCE.**—Science is worthy of study by all men, because it is so intimately associated with all the pursuits of life. The whole animate and inanimate creation is embraced within its folds. It affords ample scope for the exercise of the most comprehensive and refined intellects, as well as those of humble and moderate pretensions. The mechanic and chemist, the poet and scholar, the manufacturer and merchant, can find, in the pursuit of science, a boundless source of pleasure and profit.

**INTERNAL HEAT OF THE EARTH.**—It is well known that the temperature increases, as we descend through the earth's crust, from a certain point near the surface, at which the temperature is constant. In various mines, borings, and Artesian wells, the temperature has been found to increase about  $1^{\circ}$  Fah. for every sixty or sixty-five feet of descent. In some carefully-conducted experiments during the sinking of Dukinfield Deep Mine—one of the deepest pits in this country—it was found that a mean increase of about  $1^{\circ}$  in seventy-one feet occurred. If we take the ratio thus indicated, and assume it to extend to much greater depths, we should reach at two and a half miles from the surface strata at the temperature of boiling water; and at the depths of about fifty or sixty miles the temperature would be sufficient to melt, under the ordinary pressure of the atmosphere, the hardest rocks. Reasoning from these facts, it would appear that the mass of the globe, at no great depth, must be in a fluid state. But this deduction requires to be modified by other considerations, viz., the influence of pressure on the fusing point, and the relative conductivity of the rocks from the earth's crust. To solve these questions a series of important experiments were instituted by Mr. Hopkins, in the prosecution of which Dr. Joule and myself took part; and after a long and laborious investigation, it was found that the temperature of fluidity increased about  $1^{\circ}$  Fah., for every 500 lbs. pressure in the case of spermaceti, beeswax and other similar substances. However, on extending these experiments to less compressible substances, such as tin and barytes, a similar increase was not observed. But this series of experiments has been unavoidably interrupted; nor is the series on the conductivity of rocks entirely finished. Until they have been completed by Mr. Hopkins, we can only make a partial use of them, in forming an opinion of the thickness of the earth's solid crust. Judging, however, alone from the greater conductivity of the igneous rocks, we may calculate that the thickness cannot possibly be less than nearly three times as great as that calculated in the usual suppositions of the conductive power of the terrestrial mass at enormous depths, being no greater than that of the superficial sedimentary beds. Other modes of investigation which Mr. Hopkins has brought to bear on this question appear to lead to the conclusion that the thickness of the earth's crust is much greater than that above stated. This would require us to assume that a part of the heat in the crust is due to superficial and external rather than central causes. This does not bear directly against the doctrine of central heat, but shows that only a part of the increase of temperature observed in mines and deep wells is due to the outward flow of that heat.—*Fairbairn's Address before the British Association.*

## Editorial Notices, &c.

### AGRICULTURAL SEED AND IMPLEMENT STORE.

It will be seen from an advertisement in another column, that Mr. James Fleming has taken into Partnership Mr. G. W. Buckland in the General Seed business, wholesale and retail. Mr. Buckland has had two years experience in one of the largest and oldest Seed Establishments in London, England; and Mr. Fleming is well known throughout the Province as a Florist and Horticulturist, and for having successfully carried on the business of a Seedsman in this city, for more than a quarter of a century. The new Firm contemplate extending their business operations, and have accordingly rented a portion of the new Agricultural Hall in the course of erection by the Board of Agriculture, on the corner of Yonge and Queen streets, which they hope to commence occupying about midsummer next. In addition to a varied and extensive stock of agricultural and horticultural seeds, they purpose keeping on hand a selected assortment of the various tools and implements required by the farmer and gardener. Such an establishment in the same building, with an Agricultural Museum, which the Board has resolved on commencing, must prove both interesting and useful to a large portion of our population, especially to all such as are directly engaged in rural pursuits.

### Notice of Co-Partnership.

THE Undersigned have entered into Partnership as Seedsmen and dealers in all kinds of Agricultural and Horticultural Implements, under the firm of James Fleming & Co.

JAMES FLEMING,  
GEORGE W. BUCKLAND.

### NOTICE.

JAMES FLEMING & CO., Seedsmen to the Agricultural Association of Upper Canada, will carry on the above business, wholesale and Retail, at 126 Yonge-st., 4 doors North of Adelaide-street, until next July, when they will remove to the new Agricultural Hall, at the corner of Queen and Yonge-streets.

JAMES FLEMING will continue the business of Retail Seedsman and Florist at his old stand, 350 Yonge-street.

Toronto, January 1st, 1861.

**BOARD OF AGRICULTURE.**

THE Office of the Board of Agriculture has been removed to 188 King Street West, a few doors from the late location adjoining the Government House. Agriculturists and any others who may be so disposed are invited to call and examine the Library, &c., when convenient.

HUGH C. THOMSON,

Toronto, 1861.

Secretary.

### International Exhibition, London, 1862.

THE Commissioners for Canada at the INTERNATIONAL EXHIBITION of 1862, give notice to all parties desirous of exhibiting Canadian products, whether application has been already made for the exhibition of the same or not, that such articles may be sent in for examination and approval to the following places, at any time between the TENTH DAY of FEBRUARY next, and the undermentioned dates, viz:—

IN CANADA WEST.—London, 18th February; Hamilton, 20th February; Toronto, 22nd February; Kingston, 25th February, and Ottawa, 28th February.

IN CANADA EAST.—Quebec, 14th February; Three Rivers, 18th February; St. Hyacinthe, 22nd February; Sherbrooke, 25th February next; and Montreal, 3rd and 4th March next.

Articles will be received and stored at the Depots of the Grand Trunk Railway Company at London, Toronto, Kingston, Quebec, Point Levi, Sherbrooke and St. Hyacinthe.

The Commissioners will begin their examinations at 10 o'clock, A. M., of each day named.

Intending exhibitors must deliver the articles for exhibition at the above named places, free of charge. Should they not be approved, the Grand Trunk Railway will return them free of charge, to any depot on their line from which they have been sent.

Parties sending in Grain or Woods are requested to transmit a certificate, stating the species and varieties, and where grown. Woods should be sent of the usual dimensions for commerce, and Her Majesty's Commissioners have expressed a desire that they be shown in planks 4 inches thick, showing the sap on both sides, or in 4 inch scantling, and accompanied, wherever practicable, by twigs with leaves or flowers.

Parties desirous of further information, may apply, concerning Minerals and Specimens of Economic Geology, to Sir W. E. Logan, Montreal; concerning products of the Forests and Waters, to Dr. Tache, Quebec, or Dr. Hurlburt, Hamilton; concerning Agricultural produce, to Hon. L. V. Sicotte, St. Hyacinthe, and Col. Thomson, Toronto concerning articles of Canadian Manufacture, to Dr. Beatty, Cobourg, or to the Secretary, Montreal, to whom also, communications on all other business of the Commission are to be addressed.

R. CHAMBERLIN, Com'r, Secretary.  
Montreal, December 12, 1861.

### THE INTERNATIONAL EXHIBITION OF 1862.

THE UNITED AGRICULTURAL SOCIETIES OF WENTWORTH and HAMILTON will hold an Exhibition of Wheat at Crann's Hotel in the City of Hamilton, on Saturday the 18th day of January, 1862, with a view of obtaining the best samples to forward to the International Exhibition, London,

|                                       |     |
|---------------------------------------|-----|
| Best two bushels Soule's Winter Wheat | \$6 |
| " " " Red Chaff " "                   | 6   |
| " " " Blue Stem " "                   | 6   |
| " " " Golden Drop, Spring             | 6   |
| " " " Fife " "                        | 6   |

The Wheat obtaining the prizes to become the property of the Society. Members of either of the Societies may compete.

The wheat to be the property of the exhibitor, and grown in the County in 1861.

Entries will be received by the Secretary until 10 o'clock, a. m., of the day of Show.

WM. A. COOLEY,  
Sec., U. S. W. & H.

Ancaster, Nov. 25th, 1861.

### FOR SALE.

AT

WOODHILL, WATERDOWN P. O.

MR. FERGUSSON expects to have several pure Durham bull calves to dispose of next Spring, 1862, not intending to raise any this season. These calves will be all of the well known DUCHESS tribe, and will be put on the G. W. R. R. at six weeks old for eighty dollars each.

N. B.—First come, first served.

Waterdown, Nov. 14, 1861.

4-t.

### THOROUGH BRED STOCK FOR SALE.

THE SUBSCRIBER has for Sale Durham and Galloway Cattle, male and female.

Leicester, Cotswold, and Lincolnshire Sheep, male and female.

January 1, 1862.

JOHN SNELL,  
Edmonton, P. O., C. W.

### VETERINARY SURGEON.

ANDREW SMITH, Licentiate of the Edinburgh Veterinary College, and by appointment, Veterinary Surgeon to the Board of Agriculture of Upper Canada, respectfully announces that he has obtained those stables and part of the premises heretofore occupied by John Worthington, Esq., situated corner of Bay and Temperance streets, and which are being fitted up as a Veterinary Infirmary.

Medicines for Horses and Cattle always on hand. Horses examined as to soundness, &c.

Veterinary Establishment, Corner of Bay and Temperance Sts.

Toronto, January 22nd, 1862.

**FOR SALE.**

**A FEW PURE-BRED SOUTH-DOWN RAMS**  
and Ewe Lambs, from

**IMPORTED STOCK,**

Selected from the Best Flock-dealers in Dorset,  
Wilts, and Hants.

The Subscriber will Warrant these Lambs to  
produce as much Wool and Mutton, and of  
equal Quality, as those of Jonas Webb, or any  
other Flock of the same kind and number in  
England.

JOHN SPENCER,  
Brooklin, Post Office,

Oct. 12th, 1861. Ontario County C. W.

**AYRSHIRE BULL FOR SALE.**

**MR.** Denison, of Dover Court, offers for Sale  
a thorough bred Ayrshire Bull, bred by  
the celebrated Ayrshire breeder, John Dodd,  
Esq., of Montreal. The bull is 3 years old, and  
can be delivered at or after the Show at Lon-  
don, in September.

Toronto, Aug., 1861.

**THE****JOURNAL OF THE BOARD OF ARTS  
AND MANUFACTURES,****FOR UPPER CANADA,**

Is Published on the first of every Month,

**A**T \$1 per annum for single copies, or to clubs  
of ten or more at 75 cents. per copy; to  
members of Mechanics' Institutes, and of Liter-  
ary, Scientific, and Agricultural Societies,  
through their Secretary or other officer, 50 cents  
per annum per copy.

Subscriptions payable in advance.

Printed for the Board of Arts and Manufactures  
for Upper Canada, by W. C. CHEWETT & Co.,  
King Street East, Toronto.

**FOR SALE.**

**A** LOT of thorough bred ESSEX Pigs,—bred  
from recently imported 1st prize animals  
and who have this season taken premiums at  
both Township, County, and Provincial Exhi-  
bition.

JAMES COWAN.

Clochmor, Galt P. O., Oct. 19, 1861.

No. 2.

**Land Drainage.**

It is now a universally admitted truth by all who understand the subject, that in the temperate zone of Europe and America the under drainage of land is the foundation of all agricultural improvement. Hence laws have been passed for enabling the owners and occupiers of land to facilitate this essential operation; and the British Government have loaned large sums of money, to be repaid by an annual rent charge extending through a long series of years, for the purpose of extending an improved system of land-drainage. Some aid of this nature would no doubt be of immense benefit to Canada, provided sufficient checks could be brought to bear to prevent abuses. At best the draining of a young and extensive country like this must necessarily be a slow and progressive work, since the capital required for such operations, on an extensive scale, is very great, and at present wholly beyond the reach of the proprietors of the soil. Notwithstanding all that has been done in the old country in this way during the present century, it is astonishing to find this essential means of agricultural amelioration, can only be said to have made a commencement. Imperfect, superficial drainage is, as yet, comparatively limited. From an elaborate paper recently read before the Central Farmers' Club in London, by that eminent draining engineer, Mr. Bailey Denton, we condense the following information:

It appears that the total extent of wet lands drained or capable of improvement by draining in Great Britain alone is estimated at 22,890,000 acres, out of the total area of 56,352,000. The extent of land already permanently drained will not reach  $1\frac{1}{2}$  millions up to the present time, so that there remains undrained more than 21 millions of acres. The remaining  $33\frac{1}{2}$  millions of acres consist, for the most part, of free soils, naturally dry, which absorb and infiltrate to various depths, beyond the reach of evaporation, from one-tenth to half of the rain that falls on the surface, the rest of the rainfall being taken up by vegetation or evaporation, or passing off the surface without entering it in times of heavy and sudden rainfalls. The other portion of the  $33\frac{1}{2}$  millions consists of mountainous lands, of rock formations, the surfaces of which having rapid slopes, throw off the rainfall in very large proportions, namely, from one third to four fifths of the rainfall. Within the bounds of these steep lands there are bogs and moors, which catch a large quantity of the water thrown from the mountain slopes, and give off by evaporation much more moisture than the rain which falls directly upon them. The extent of the surcharged free soils drained or requiring draining is about 12 millions out of 23 millions of wet lands, leaving of clays about 11 millions. These figures are set forth to draw attention to the magnitude of the field to which under-drainage is gradually extending itself, and for which provision must

be made sooner or later in the main arteries and outfalls. The depth of drains required by the commissioners, before a rent charge on the land is allowed must not be less than four feet.

From the above facts it appears that in Britain there is enormous scope for the improvement of wet lands for many years to come; drainage companies and agricultural engineers will all have abundant work on their hands; and it is equally plain that their labor will be facilitated and made successful on all clay lands by the agency of the steam plough.

### Growth of Red Clover with Different Manures.

In the valuable paper on the culture of this valuable plant by the application of special manures, in a recent number of the *Journal of the Royal Agricultural Society of England*, by that scientific and extensive experimenter, Mr. J. B. Lawes, some very interesting and suggestive facts are stated; some of the more important of which we will state in a much abridged form.

The experiments on Mr. Lawes' farm satisfactorily show that some of the crops that are generally grown in rotation will yield a larger amount of produce year after year on the same land, on the application of certain constituents as manure. Thus, a part of the same field, in which the experiments on clover now in question were made, has grown barley for ten years in succession, and on some plots large crops have always been obtained. In like manner, in an adjoining field, wheat has been successfully grown for sixteen years consecutively. Nor is there at present anything in the results to lead to the supposition that these crops might not be so grown continuously for a century.

The results, however, of similar experiments with clover are very different. The practical conclusions derived from a careful comparison of the experiments may be thus very briefly stated:—When land is not what is called "clover sick," that is from exhaustion not

capable of producing a healthy crop at all, the produce of clover may frequently be increased by top-dressings of manure containing potash, gypsum, and super-phosphate of lime; but the high price of salts of potash, and the uncertainty of the action of manures upon the crop, render the application of artificial manures for clover a practice of doubtful economy. On land termed "clover sick," some of the ordinary manures, whether "artificial" or natural, can be much relied upon to secure a crop. So far as our present knowledge goes, the only means of ensuring a good crop of red clover is to allow some years to elapse before repeating the crop upon the same land.

In works on agriculture the failure of clover is accounted for in a great number of ways, among which the following assumed causes may be mentioned:—Exhaustion of the soil by over-cropping and non-manuring; the growth of parasitic plants, which strike their roots into the clover and exhaust its juices; destruction by insects; the injurious influence arising from the matter excreted by the roots of the former crop, or from the decay of the roots themselves; the growth of the young plant under the shade of a grain crop. Although the clover crop may be found to suffer from more than one of the above-mentioned causes, the phenomena which present themselves are nevertheless by no means satisfactorily explained; and so far as prevention is concerned, our knowledge is pretty nearly limited to that of the fact, that the only chance of growing the crop with success is to allow a certain number of years to elapse before repeating it on the same land.

Although clover is generally a more certain crop on this side of the Atlantic than in the old countries of Europe, still even here of late years it has become somewhat precarious on land that has been long under tillage in the ordinary way; and either special manures, or rest,—that is, repeating the crop at longer intervals,—must be given, in order to bring about the former state of productiveness. Much injury is often done the cultivated grasses as well as grains, by the foul state in which the former are often sown. *Clean seed*

is a matter of the utmost importance. Farmers in general are quite unaware of the extent of the mischief which they thus suffer. In a single pint of red clover as many as 1,600 seeds of plantain have been found; and in a pint of white clover have been detected by careful observation by means of the microscope, 11,200 small seeds of various kinds of weeds! It thus becomes easy to account for the dirty state into which much of our pasture as well as arable land has fallen.

### Care and Food of Live Stock.

At this inclement season of the year, the farmer's best attention should be devoted to the management of his live stock. Not only should shelter and warmth be provided, but special care must be bestowed on all matters relating to cleanliness, feeding, and ventilation. In this country, animals suffer more from want of systematic feeding and cleanliness than from cold, a low degree of which they can tolerably well endure, if unaccompanied with dampness. It is fortunate that in our severest weather, the atmosphere is generally still and dry. With buildings properly constructed, so as to prevent cold currents of air, and yet admit a sufficiency of that essential element, stock, with due attention to cleanliness and feeding, may be carried through our long and severe winters without any extraordinary difficulty, or risk of their health.

The use of straw as food to cattle forms a portion of a very valuable prize essay of Mr. Evershed, which appeared in a recent number of the *Journal of the Royal Agricultural Society of England*. The writer is of opinion that, although it is a common plan in many of the grazing districts of England, where roots are comparatively scarce, to feed store cattle on about 20lbs. of straw and 3lbs. of bean meal, yet that they do better on straw with roots *instead of meal*, even when the supply of roots did not exceed  $\frac{1}{2}$  cwt. per head, a day. Cattle wintered on straw and meal only became "hide bound," with staring coats. It is calculated that the average production of straw per acre is  $2\frac{1}{2}$  tons; that not more than four cwt. of straw enters into the composition of a ton of farm

yard manure; the remainder being, excrements 6 cwt. and rain water 10 cwt. The consumption of straw-chaff by a cart horse is put down at one ton per annum, at least; cattle at 21 cwt. per annum; and for the sheep on a farm of 400 acres, 8 tons of straw-chaff yearly. On an arable farm of 400 acres, therefore, Mr. Evershed calculates that there is required for the fodder of 50 head of large stock, whether horses or beasts, at least 50 tons; for sheep 8 tons; for storing roots, when wheat is reaped, waste from thatching, making foundation of stacks, &c., say 5 tons; total 63 tons of straw. This article of straw, when finely reduced by the chaff-cutter, is more readily eaten by animals generally.

We also find in the same number of the Society's Journal, an interesting report by Professor Voelcker, on the results of his experiments, which appear to have been conducted with great care and originality, on the feeding properties of several substances. The following results of his analysis of two varieties of Kohl-rabi, of cabbage, and of mangel wurzel, and of the repose pulp after its distillation, will be interesting to our readers:—

|                                                    | Green top. | Purple top. |

A comparison of the preceeding results, with the analysis of swedes, mangels, and turnips, shows that theoretically kohl-rabi is much more nutritious than white turnips, and fully equal, if not superior, to swedes and mangels.

The composition of the heart and inner

leaves of the cabbage was proved to be as follows:—

|                                    |       |

Cabbages contain about the same proportions of water, sugar, and protein compound as are found in good swedes. It appears that cabbages and swedes, weight for weight, possess nearly the same nutritive value.

There is nearly  $3\frac{1}{2}$  per cent. more water in the pulp than in the mangel. The decomposition of one specimen of each dried at  $212^{\circ}$  was found by Dr. Voelcker to be as follows:—

|                                                                      | Mangels. | Pulp. |

| Equal to protein compounds ... | 8.76 | 14.92 |

The Professor adds:—"A careful consideration of the differences just pointed out in the composition of pulp and roots will enable us to decide with no great difficulty—1st. That weight for weight, pulp similar to that analyzed by me cannot possibly have the same feeding value as good mangel-wurzels. 2nd. That such pulp, however, is a refuse material which possesses high feeding properties."

### Adulteration of Seeds.

It would appear, at first sight, an unnecessary thing to remind farmers and gardeners of one of the most important and self evident truths connected with the practice of their art, viz., the

importance of exercising the greatest care in selecting *pure and sound seed*; but observation and experience too plainly show that in numerous instances, such precautions are in a great measure practically disregarded. Hence it is that both our farm and garden crops are not only inferior both as regards quantity and quality, but the soil is filled with pernicious weeds, most difficult and expensive to eradicate.

In a recent number of the English Agricultural Society's Journal, there is a valuable paper on this subject, by the Messrs. Raynbird, of Essex, who are among the most extensive and respectable seed-growers in Britain. The following facts, chiefly taken from that article, cannot fail to interest our readers on this side of the Atlantic, where it is to be feared a great many old and impure seeds, partly, perhaps, because they are sold cheap, are extensively purchased, to the great loss and annoyance of our farmers and gardeners.

Seeds are adulterated with old seed and with dead seed, and with other seed. Thus clovers of the last year's growth are mixed with the remainders of old stocks, either dead or with vitality impaired—red clover is mixed with the cheaper article trefoil—white clover with red suckling, when that happens to be the cheaper of the two, and it is moreover sometimes colored to make it resemble alsike clover.

Turnip seeds, too, are mixed with dead and refuse samples and with rape seed, sometimes killed to save detection in the crop.

Rye grass seed is mixed with seed of the worthless *Holcus lanatus*—soft meadow grass; and the high-priced Italian rye grass is especially liable to adulteration of this kind, though its awn should make any admixture with it easy of detection. Let us here quote from Mr. Raynbird a passage indicating the general prevalence of dishonesty of this kind:—"Although with the farmer and country dealer some of the London trade get the credit of these tricks, they sometimes extend to the country; as shown by the following transaction, in which I was personally concerned. Some five or six years since, towards the end of the seed season, I bought of a well-to-do country dealer, who has a high reputation for respectability, and who has (it is said) amassed a large fortune by his dealings, some 50 or 60 quarters of what appeared to be a fine parcel of Italian rye grass, the want of the usually characteristic awn on a part of the seed being attributed to over-ripening, or some such cause. This sample was immediately resold to Mr. William Skirving, the well-known seedsman of Liverpool, one of the most straightforward and honorable men in the trade, who made a

request for immediate despatch. Accordingly, dependence being placed upon the honesty and reputation of the country merchant, the 50 or 60 quarters were forwarded on from London without the usual examination there. When the seed was inspected in Liverpool it was found to contain a large percentage of light Scotch rye grass so carelessly mixed that when shot out of the bags the seed showed a streaky appearance, giving plain evidence of the impostor's practices. Accordingly the seed was returned; but, as it was sold for delivery in London, its removal thence without examination prevented me, by the custom of the trade, from enforcing the claim to compensation; although it is very doubtful, I believe, whether the law would not have given me redress, and a sound legal decision on this point would be of great service to the trade."—It is, however, more, perhaps, from the carelessness than the dishonesty of dealers that the farmer suffers, and under this head the injury inflicted is in point of fact inflicted by himself. Seeds of crops are mixed with seeds of weeds, owing to the carelessness of the grower; and this is an injury to the buyer of greater magnitude than any which is suffered by the intentional admixture of dead or worthless seeds with a genuine sample.

Weeds are no necessary growth amidst our crops. The plant appears because the seed is in the soil; and it continues to appear, notwithstanding cultivation, because the cultivator sows its seed. In grass fields many weeds continue to arise because mown after the seeds are ripe; and in arable lands the hoe sows often a myriad in the act of destroying one. The scythe and the sickle scatter broadcast what ought never to be allowed to ripen; and the drill and hand in depositing our wheat and other grain, our turnip seed, sainfoin, clovers, grasses, &c., *sow and carefully deposit*, and harrow in as many seeds of weeds as seeds of cultivated crops. And not only does the hoe, and the scythe, and the wind, and the sowing machine, scatter weeds broadcast over our fields, but the dung cart also is full of them. So long ago as the meeting of the Agricultural Society at Southampton we remember seeing plots of grasses which had been manured with farm yard dung compared with other plots on which (broadcast) guano, nitrate of soda, &c., had been used. The artificial manures contained no seeds of weeds; but it was plain that the dung cart had been full of them. When pure seed shall be sown, and no opportunity given in any way for the return to the land of any other than the seed of our cultivated crops, then we may hope that the hoe will ultimately clear the land of weeds; but as long as the farmer sows their seeds he must expect to reap their produce.

We take the following illustration of our subject from a recent number of Morton's Farmers' Almanac:

The impurity of farm seeds, owing to the presence of weed seeds, has been fully investi-

gated by professor Buckman, of Cirencester College, who has published his results in the *Agricultural Gazette*. The following table describes the character of one series of samples of seeds, to which his attention had been drawn by a correspondent:—

| Name.                                    | Weed Seeds to the pint Imperial | Weight of 2 oz. by measure. | Remarks on Principal Weeds, &c.                                                                                |
|------------------------------------------|---------------------------------|-----------------------------|----------------------------------------------------------------------------------------------------------------|
| 1. White Clover .....                    | 128,000                         | .....                       | Caryophyllæe, Polygonaceæ Composite, Myosotis, Scrophulariaceæ, &c.                                            |
| 2. Red Clover .....                      | 16,960                          | .....                       | Plantain, Myosotis, Caryophyllæe. Of these 9600 seeds were those of Plantain.                                  |
| 3. Cow-grass Clover .....                | 12,160                          | .....                       |                                                                                                                |
| 4. Rib-grass - Plantago lanceolata ..... | 1920                            | .....                       | Polygonaceæ—Dirt and stones.                                                                                   |
| 5. Italian Rye-grass .....               | 2200                            | 172 grains.                 | Ranunculus repens, Holcuslanatus, Bromis mollis, Bromus, Holcus, Triticum repens, Arrhenatherum avenaceum, &c. |
| 6. Cockfoot .....                        | 3440                            | 124 "                       | Holcus, Rye-grass, &c., very dirty.                                                                            |
| 7. Smooth-stalked Meadow Grass .....     | 19,000                          | 160 "                       | Holcus, Rye-grass, &c.                                                                                         |
| 8. Crested Dogtail Grass ..              | 6400                            | 360 "                       | Bromus mollis, &c.                                                                                             |
| 9. Meadow Foxtail Grass ..               | 19,200                          | 52 "                        | Nearly half Holcus lanatus.                                                                                    |
| 10. Meadow Frenche Grass ..              | 3200                            | 200 "                       | Holcus lanatus.                                                                                                |
| 11. Sweet-scented Vernal Grass .....     | 1600                            | 100 "                       | Caryophyllæe and small weeds.                                                                                  |

The first example in this list may well astonish our readers. *One hundred and twenty thousand weeds* to a pint of clover seed! This, allowing 12 lbs. to an acre, should give to a square yard of ground a quantity more than sufficient to crop the soil; and if we consider that clovers are at best a slow and shy growing plant, and that the weeds detected in this particular sample come to perfection so rapidly as not unfrequently to produce two crops of seed in a year, we need scarcely wonder that the land should so often be pronounced as "clover sick;" for while there is no denying the condition to which this designation has been given, yet recent observations have led to the conclusion that in cases

of well-prepared land in good condition for a clover crop, sown weeds—to say nothing of those previously in the soil from seeding on the land as the result of dirty farming—have been the cause of failure. Our limited space hinders any enlargement on this subject; but we commend the above table to the attention of our readers, as describing the most important fact in agriculture to which this little book this year refers.

The following is Mr. Raynbird's advice to buyers of seeds, in order to the detection and punishment of roguery:—

1st. To select a responsible and respectable seedsman, and not to seek goods at the lowest price and of the lowest value; if he does this, a seedsman can no doubt supply a cheap article, but can he recommend it? 2nd. To purchase seed with a warranty that a certain percentage of the seed will vegetate; the warranty to cover the value of the seed, or more, if necessary. 3d. To try a certain number of seeds, both in a hot-bed and in the open ground, and see what proportion vegetates: the first plan speedily showing the actual number of living seeds—the second what number would probably grow under open air culture. 4th. to examine seeds him with a microscope, that he may detect the percentage of weed adulterations; the microscope, carefully used, would probably detect not only this but the new or old, doctored or mixed nature of seeds—a single glass is sometimes used now, but a microscope of tolerably high power would be far more efficacious. 5th. To note that the adulteration of rye-grass by admixture, however carefully done, may be detected easily when one seed is lighter than the other; the winnowing machine will separate each according to their respective gravities. 6th. To get good genuine samples of similar seed, with a view to a comparison with that purchased both by the eye and by floating the two in water as a test of comparative gravity. 7th. Since, however simple these modes are, many persons will be too much engaged to try them, and will buy seed just before sowing and put it in the ground with merely a cursory examination; why should we not adopt the practice of taking a sample for examination by a scientific botanical examiner, that he may determine the percentage of weeds and of live seeds, just as we have chemical analysis to examine artificial manures? A few shillings thus laid out might save pounds.

To conclude, the adulteration of seeds is a practice of trade, or rather a system of fraud similar to that of falsely labelling goods for sale: as when a hundred yards of cotton thread are labelled as 200; or a tin of coffee stated to weigh 2 oz. or 3 oz. more than its true weight. But there is this difference in these latter instances, that the buyer of the cotton or the coffee suffers an immediate and direct loss, the amount of which can be at once estimated; but the loss to the buyer of doctored seeds is far greater, affecting all the expected increase of

the fruits of the earth, if not permanently tainting the soil on which they grow. In honourable trade things should be called by their proper names, and if it is necessary to have mixed and doctored seeds they should be sold as such.

Adulteration plainly owes its origin to the desire to amass wealth and, so long as the demand for cheap goods continues, I fear it will be pandered to by the unscrupulous trader. Dr. Buckman's words in the "Journal," vol. xvii., p. 376, may prove a fitting conclusion: "Pure or clean seed is ever worth paying a greater price for, as the reverse may entail trouble and expense for years. Any mechanical processes, therefore, which can be made available for cleaning seed are well worthy of patronage. A seedsman who will be careful in the preparation and collection of seed deserves the best support. In order also to assist in this matter, farmers should be particular not to allow a dirty patch to stand for seed, although it may be 'the most profitable thing they can do with it.'"

### Mean Temperature of the Year 1861.

We have been obligingly furnished with the following table, showing the mean temperature of each month of the past year, with the difference from the average, by Mr. Sergeant Walker, of the Toronto Meteorological Observatory:

| MONTH.         | MEAN TEM-<br>PERATURE. | DIFFERENCE<br>FROM THE<br>AVERAGE | REMARKS.                       |
|----------------|------------------------|-----------------------------------|--------------------------------|
| January.....   | 19.6                   | —3.67                             | Alternately<br>Warm &<br>Cold. |
| February.....  | 26.06                  | ×3.08                             |                                |
| March.....     | 26.92                  | —3.21                             |                                |
| April.....     | 42.02                  | ×1.04                             |                                |
| May.....       | 47.50                  | —3.89                             | Cold.                          |
| June.....      | 61.29                  | —0.07                             |                                |
| July.....      | 65.37                  | —1.48                             |                                |
| August.....    | 65.48                  | —0.54                             |                                |
| September..... | 59.07                  | ×1.16                             | Warm.                          |
| October.....   | 48.74                  | ×3.22                             |                                |
| November.....  | 37.14                  | ×0.45                             |                                |
| December.....  | 31.13                  | ×5.02                             |                                |
| Mean.....      | 44.21                  | ×0.09                             | Mild.                          |

### Leached Ashes as Manure.

EDITORS "AGRICULTURIST,"—Would you be good enough in your next issue to give a little information as to the value of *Leached Ashes* as a manure for general purposes. Their value *unleached* is well known, but after coming from the soapers their value must be greatly diminished. Alone, would they be sufficient for turnips, or wheat, or corn—say 20 tons per acre? or must they be combined with other composts?

Last year I applied *coal* ashes, with the cinders, over land on which a week after I planted corn, and sowed a patch of turnips. Both corn and turnips were greatly injured. The corn on which stable manure was used was green, and gave good ear, while that on the ashes was yel-

lowish and very poor. And as for the turnips, (and they were well worked,) not one grew bigger than a good sized potato. Can they not be used advantageously?

Is bone dust equally good for carrots and turnips and mangels? Kindly say where the *dust* can be had, and at what price?

Your kind attention will oblige,

Yours respectfully,

ROBT. MACAULAY.

HAMILTON, January 1862.

#### REMARKS.

The ashes of plants differ materially in their composition, not only as regards the various species, but also the same variety of plants will yield ingredients, in different proportions, according to the nature of the soil, the mode of culture, and the character of the season. The manuring power of ashes, therefore, cannot be estimated by any fixed standard. Wood ashes always contain a considerable amount of carbonate of potash, lime, &c., and are consequently very beneficial to such plants as require large quantities of these alkalies, such as Indian corn, turnips, beets, and potatoes. *Leached ashes* have lost much of the principal alkaline salts, and have been deprived of the greatest part of their most important soluble ingredients; still they must not be regarded as an unimportant fertilizer, as the lime and other mineral matter which they contain is always more or less beneficial to the soil. Unless the land is well worked and contains sufficient *organic* matter, we should not consider ashes, whether leached or unleached, as *alone* adequate to the production of a good crop of wheat, turnips, or corn.

Leached ashes we should recommend, as a general rule, to be used as a compost, or with other materials abounding in the organic elements; that is, containing vegetable and animal matter.

Coal ashes rank much lower in the scale of fertilizers than those derived from wood. Their chief value as a manure consists in the quantity of earthy salts they contain. Especially sulphate of lime, and more or less of the phosphate of magnesia. After all, their mechanical action on certain soils is, perhaps, more beneficial than their chemical, particularly on very heavy, adhesive soils, destitute of lime. In such soils coarse coal-ashes, when applied in considerable quantity, and thoroughly incorporated with the

soil, by deep ploughing or digging, tend very much to lighten it, by permanently opening up its pores, and thereby affording free admission of air, heat, and moisture. On very light soils, which are naturally too loose and porous, the action of coal ashes may prove positively injurious, by giving greater intensity to these qualities. This may have been the case with our correspondent, who does not state whether his soil is stiff or light, nor its condition in relation to organic matter. We should certainly not recommend the application of coal ashes to light, hungry soils, except, perhaps, as a top dressing for grass or clover.

Bone dust may be relied on as an excellent manure for turnips, carrots, mangels, &c., and it possesses great value as a dressing for most of the cereal crops, particularly old pastures. The most reliable and economical way, perhaps, of using it, is in a compost with other things,—such as farm-yard dung, ashes, rotten leaves, scouring of ditches, &c. It would be well if a bone mill was erected in the vicinity of all our principal towns and cities, as the quantity of manuring matter lost from this neglected source alone is beyond all calculation. Mr. Lamb, of Toronto, has had a bone-mill in operation for several years, and many of his customers, we happen to know, have been well satisfied with the result of their trials. Mr. Lamb's prices are 50 cents per bushel, crushed coarsely; and 60 cents for half inch and dust. He allows 15 per cent discount on all orders of not less than \$100. We will shortly take up the consideration of the matters involved in our correspondent's communication more in detail.

#### The Agriculturist.—Correspondents Wanted.

EDITOR OF THE CANADIAN AGRICULTURIST.  
—Dear Sir,—I have just received the last number of the *Canadian Agriculturist* for 1861, and I must say that I am highly gratified with its improvement, especially for the last year, therefore I do not hesitate to say that it stands not No. 2 to any of the American Agricultural papers that we get from our neighbours. But there is one feature lacking, namely, a greater amount of correspondence, which I frequently hear you complain of. If this could be obtained it would add much to the popularity of your valuable paper. I think the cause of this must be the high postage. Men do not like to give

information and then have to pay for it. But I will come to a conclusion, with the remark that your paper is like a winter apple, ripening better and better.

R. B. WERDEN.

Picton, Prince Edward, Jan. 20, 1862.

### Patents of Invention.

We extract from the official Gazette the following list of patents issued for agricultural implements and machines:

BUREAU OF AGRICULTURE AND STATISTICS,  
Quebec, 15th Jan., 1862.

His Excellency the Governor General has been pleased to grant Letters Patent of Invention for a period of Fourteen Years, from the dates thereof, to the following persons, viz:—

Heman Hazleton, of the Township of Townsend, in the County of Norfolk, Carpenter, "An Improved Self Propelling Gate"—(dated 21st May, 1861.)

Silas Welte, of the village of Princeton, in the County of Oxford, Cabinet Maker, "An improved Churn, termed the 'Blenheim Churn.'"—(Dated 22nd May, 1861.)

Robert Kerr, of the township and county of Waterloo, Yeoman, "A Grain and Seed Broadcast Sower."—(Dated 24th May, 1861.)

George A. Carman, or the village of Morrisburgh, in the county of Dundas, Carriage Maker, "A Vegetable Root Cutter."—(Dated 28th May, 1861.)

Michael Clair, of the township of Sophiasburg, in the county of Prince Edward, "The Excelsior Washer."—(Dated 4th June, 1861.)

James McKelvey, of the town of St. Catharines, in the County of Lincoln, Tinsmith, "A Refrigerator termed the 'Prince of Wales' Cupboard Refrigerator."—(Dated 25th June, 1861.)

Elias Vanderwater, of the township of Sidney, in the county of Hastings, Machinist, "An improved Reaping and Mowing Machine."—(Dated 17th July, 1861.)

Henry Fryatt, of Aurora, in the County of York, Carpenter, "Rotary Tooth for Harrows." (Dated 17th July, 1861.)

George Deans, of the town of Port Dover, in the county of Norfolk, Mechanic, "A Challenge Washing Machine."—(Dated 18th July, 1861.)

Almas A. Knowlton, of the township of Brome, in the county of Brome, "A Washing Machine."—(Dated 18th July, 1861.)

John Pike, of Prescott, in the County of Grenville, as assignee of John G. Frazer, of the aforesaid place, Barber, "An improved Churn."—(Dated 30th July, 1861.)

Charles R. Parkes, of the City of Toronto, in the County of York, Turner, "An improved Churn."—(Dated 30th July, 1861.)

Peter McEwen, of Russell, in the county of Russell, Farmer, "An improved Plow."—(Dated 30th July, 1861.)

Abiel O'Dell, of the Town of Bowmanville, in the county of Durham, Machinist and Builder, "A Self-regulating Spiral Spring Mangle and Washing Machine."—(Dated 3rd August, 1861.)

John Powers, of the town of Stratford, in the county of Perth, Builder, "The Victoria Washing Machine."—Dated 3rd August, 1861.)

Richard H. Oates, of the city of Toronto, in the county of York, Manufacturer, "A Self-revolving Wind-Mill House with circular foundations."—(Dated 9th August, 1861.)

David Elm Norton, of the town of Bowmanville, in the county of Durham, Machinist, "An improved Churn, termed 'Norton's Horizontal Screw Dash Churn.'"—(Dated 10th August, 1861.)

Robert Webber, of the township of East Zorra, in the county of Oxford, Yeoman, "Webber's Scarifier or Field Cultivator."—(Dated 20th September, 1861.)

William and Thomas Walker, both of the township of Chinguacousy, in the county of Peel, Carpenters, "The Ocean Wave Washing Machine."—(Dated 29th Nov., 1861.)

C. S. Shannon, of the city of Hamilton, "An improved Driving Rein."—(Dated 29th Nov., 1861.)

Henry Dodd, of the township of Goderich, in the county of Huron, "Improved Sieves or Screens for Fanning Mills."—(Dated 29th November, 1861.)

Volney O'Brien, of the town of Guelph, in the county of Wellington, "The Excelsior Churn."—Dated 29th Nov., 1861.)

James G. Thompson, of the town of Peterborough, Gentleman, "An Automatic Gate."—(Dated 29th Nov., 1861.)

Asa Jarvis Foote, of the village of Tilsonburg, in the county of Oxford, "A new and useful Washing and Scouring Machine."—(Dated 29th Nov., 1861.)

Hugh McLaren, of Lowville, in the county of Halton, "A combined Seed Drill and Cultivator."—(Dated 29th Nov., 1861.)

N. H. Nutting, of the township of Marysburg, in the county of Prince Edward, "The Ontario Washing Machine."—(Dated 29th Nov., 1861.)

William Depew, of Paris, county of Brant, Tinsmith, "A Balance Gate."—(Dated 29th Nov., 1861.)

### On Feeding Stock.

The following lecture on Feeding Stock was delivered by Dr. Anderson, chemist to the Highland Agricultural Society of Scotland, at its annual meeting in Edinburgh, December 18th,

1861. It will be found interesting and useful to our readers generally. Eds.]

In an address given at the Edinburgh show, in the year 1859, I took up the subject of the feeding of stock as a branch of farm management, and discussed the general principles on which its prosecution depends, referring more especially to the nature of the food and its use in such a manner and in such quantities as are necessary to secure a proper proportion of the great classes of nutritive compounds required to maintain the vital functions in a state of healthy action, and the particular conditions under which the constant wastes of the tissues may be reduced within the narrowest possible limits, and the quantity of food required to supply the place of the effete matters thus diminished to the greatest extent. These matters, in fact, include the broad principles which must be kept in view in the feeding of all animals, and practice has arrived at conclusions in harmony with them, by studying, in the first instance, the natural instincts of the animals, and observing the kinds of food they prefer, and then by mixing the different substances in different proportions, and otherwise varying the mode in which they are supplied to the animal. It has thus come to be well known that certain foods and mixtures produce a better effect than others, some kinds fattening quickly and giving the animal those qualities which the butcher seeks, and others producing a much less favourable result. Looking at the subject in a practical point of view, it becomes, of course, most important to prosecute it into detail, and to ascertain the most economical method of arriving at the required result, and by a systematic series of trials it is possible to obtain an accurate knowledge of the kinds and quantities of food capable of replacing those in common use, and to make mixtures which fulfil the same end with greater economy. A great part of this knowledge has been attained by experience—that is, by a succession of trials extending over a very long period of time, and many of which have, in one sense, proved failures, inasmuch as they showed that particular mixtures were uneconomical, and a source of loss to those who used them, although in another sense, they were not failures, because they showed what ought to be avoided. If it were possible to go back over the whole range of trials by which our practical knowledge of the best proportions and kinds of food has been acquired, it would, no doubt, be found that, as in most instances, experience has been bought at a very high price. It is only after often-repeated observations that it can arrive at incontestible conclusions, and herein it is that science differs from experience. The results in both are obtained by observation, but science has systematised observation, and has coupled with it the explanation of the facts observed. It starts from the knowledge acquired by experience, seeks to discover the *rationale* of every fact, and

endeavours to generalize and classify them.—Thus, if it has discovered, for example, that a particular food known to give unfavourable results is deficient in some particular element, it then proceeds to try whether the addition of that substance will increase its nutritive effects; and if this proves to be the case, it is justified in inferring that every other food in which that element is wanting will also prove disadvantageous in practice. The tendency of science, therefore, is to diminish the number of trials which end in loss, and thus to acquire practical knowledge with greater rapidity and economy. It is obvious, however, that science cannot in all, or even in many instances, predicate with absolute certainty the exact extent to which particular foods are likely to be advantageous in practice; but this is owing in a great measure to our still imperfect knowledge of the complicated mechanism of the animal frame; and no one who knows either this or the various disturbing causes which interfere with the results when vital processes come into play would for a moment venture to indulge in dogmatic assertions, but would rather look upon science as fitted to direct experiment and supply a class of facts which may form the groundwork of further practical observations.

The position which science is capable of taking may be best illustrated by a particular example, and for this purpose we may select the facts connected with the use of rape cake as a feeding stuff. Chemistry has shown that, so far as the proportion of nutritive matters contained in that substance is concerned, it is completely on a par with linseed cake, which sells at double the price, but it has also established the fact that it contains a small proportion of a peculiar bitter principle of a resinous character associated with its oil. Now, it is well known that some bitters are not unpalatable to cattle, while others are very offensive; but it is not possible by analysis alone to foretell whether any such substance belongs to the one or the other category, that being a matter which can only be decided by observing the effect it produces on the animal itself. At this point, therefore, the function of science ends, and that of practical observation begins; and it has been found in practice that—owing, no doubt, to the presence of this substance—rape cake cannot be given with the same freedom as linseed cake, because, when consumed in large quantity, its disagreeable taste affects the animal, although when used in smaller proportion and mixed with palatable substances it proves highly nutritious. These facts having been determined, a further progress may be made, and science may proceed to inquire whether it lies within its resources to devise a process by which the objectionable constituent may be removed and the substance thus placed on a level, with the most favored food, while practice may study the best method of concealing its taste or otherwise palliating its bad effects. When the study of the principles of feeding is

prosecuted into detail, many subjects of great interest and importance offer themselves for consideration, and of these not the least worthy of notice is the best method of making the food consumed fully available to the animal. It has been clearly established that only a very small proportion of the nutritive matters of the food is stored up within the body in the form of flesh and fat, and that even under the most favorable circumstances by far the larger proportion is practically wasted, or at least reduced to the less valuable form of manure. It is known also that the quantity stored differs greatly in different animals; thus, the pig makes a much better use of its food than the ox, for it will increase in weight nearly twice as much with the same consumption of food. The same is true, though to a more limited extent, with regard to individuals of the same species, and every one knows that some cattle fatten more quickly than others. These differences are, no doubt, often due to constitutional peculiarities which cannot be overcome in practice; but it cannot be questioned that it is a matter of the greatest possible moment to determine the circumstances under which the waste can be reduced to a minimum, and the animal be made to assimilate the largest possible proportion of the food which enters its stomach. It is very obvious that the complete solution of this problem involves many nice physiological questions, and in the present state of our knowledge is scarcely possible; but there are individual departments of the subject which may be considered, and to one of these I propose directing your attention on the present occasion.

The particular question I intend to discuss is how far the nutritive value of a food may be increased by adding to it certain accessory substances which are not themselves *foods*, in the proper sense of the term, but which, either by maintaining the general functions in a state of health, or by promoting digestion, facilitate the assimilation of the true food. My attention has recently been directed to the subject in the course of some experiments, to which reference will afterwards be made, but which I shall here discuss only in a general point of view. Substances added to the food in this way are commonly known by the name of "condiments," and are understood to operate by promoting the healthy exercise of the digestive organs. The mode in which they do this, however, is not well defined, and cannot in all cases be identical. We ourselves use a vast variety of those substances, but we do so without any definite object, and most of them have probably no other effect but that of pleasing the palate, and are, therefore, very far from acting favorably, but rather induce the ingestion of a larger quantity of food than the stomach can properly dispose of, and, consequently, check, instead of promote the progress of digestion. On the other hand, if we are to argue from our natural instincts and the universality of their use, there are substances which must be beneficial. Experience has led us to the use of

certain mixtures of food, which are often considered to be mere manifestations of popular fancy, but which are really founded on natural laws, thus, for example, we eat beans and bacon, and thus conjoin a very fat feed with the most highly nitrogenous vegetable. In the same way, the Irish laborer who consumes a large quantity of the starchy potato uses along with it a great deal of milk, so as to supply the nitrogenous and fatty substances the system requires. It is reasonable, therefore to assume that the use of condiments is dictated by the necessity for them. If, then, the subject is important in regard to human beings, it is still more so in relation to the feeding of cattle, which, in their artificial state, cannot select for themselves, but must take what the feeder supplies.

The most important of all condiments to animals is unquestionably salt, and if we are to assume that their natural instincts lead them to take what is beneficial, we can have no doubt as to its utility. The desire for it is shown by the avidity with which cattle consume it when lumps of it are placed in their feeding troughs, and that this is not the effect of the artificial state in which they are kept is proved by the fact that any spot where it exists is sure to become the resort of wild cattle. Such spots are not uncommon in the back woods of America, where they are known by the name of "salt licks," and the ground around them is constantly covered with the footprints of innumerable herds of wild cattle. So familiar is the desire of cattle for salt that in our colonies it is well known that the most effectual method of preventing them from straying is to place abundance of salt at their disposal in the neighborhood of the stations at which they are kept. Beyond all question, then, salt must be in some way advantageous to animals. Let us see whether it is possible to find any reason for this. If the different parts of the animal body be examined, the quantity of salt contained in it is found to be far from inconsiderable. Thus—

|                            |                |
|----------------------------|----------------|
| Human blood contains ..... | 0.42 per cent. |
| Milk .....                 | 0.02 "         |
| Horses' blood .....        | 0.51 "         |
| " chyle .....              | 0.53 "         |
| " urine .....              | 0.29 "         |
| Ox urine .....             | 0.01 "         |
| Pig urine .....            | 0.52 "         |
| She p urine .....          | 0.63 "         |

It is clear, therefore, that a considerable quantity of salt is indispensable for maintaining the supply required by the system. Thus, a horse excretes daily about 20lbs. of urine, containing nearly 400 grs. of salt. If, now, we look to the food as the source of this supply, we are struck by the small proportion of common salt which many of them contain. This quantity is exceedingly variable, and depends to no small extent on the nature of the soil on which the crop was raised, proximity to the sea, &c.; but the following tables give in grains the average quantity

contained in 100 lbs., of the more important kinds of cattle food:—

|                             | Grains. |
|-----------------------------|---------|
| Meadow hay.....             | 2940    |
| Clover hay.....             | 2380    |
| Oat straw.....              | 840     |
| Turnips.....                | 770     |
| Red clover (fresh).....     | 630     |
| Beans.....                  | 560     |
| Peas.....                   | 315     |
| Oats.....                   | 210     |
| Potatoes.....               | 158     |
| Rye straw.....              | 79      |
| Barley and wheat straw..... | traces. |
| Barley and wheat grain..... | traces. |

It is at once obvious from the examination of this table, that in only a small number of the common kinds of food is there a considerable quantity of salt, and many of the most important substances are altogether devoid of it. It is particularly worthy of notice also that hay, which may be described as the natural food of cattle, contains it in abundance, and hence, when feeding on it, the animals may obtain all that is absolutely necessary for their health, but when they are placed upon some of the mixtures of food now in common use—such, for example, as turnips and straw—the quantity may be too small for their requirements. If to these considerations we add the necessity for salt to supply the hydrochloric acid which is found in the gastric juice, and the other uses which it fulfils in the system, we can entertain but little doubts as to the importance of an adequate supply of it for maintaining in a healthy state the functions of the animal, while it is also manifest that the quantity required for this purpose is mainly dependant on the nature of the food. Proceeding further to inquire into the influence which salt exerts in causing the animal to exhaust more completely the food supplied to it, and to store up a larger quantity, the results obtained by different experiments are very conflicting. The subject has been examined very carefully by Boussingault. He took six young cattle, which he divided into lots of three each, so as to secure as perfect uniformity as possible, and to the one he gave no salt, to the other he gave it in the proportion of 525 grains per head daily. After some time both lots were weighed, when it was found that the lot which had got salt had gained 10.5 lbs. for every 100 lbs. of initial live weight, while those which did not get salt had gained 11 lbs. In this respect the animals were restricted to a fixed quantity of food; but another was made, in which they were daily supplied with more than they could consume, and the residual quantity weighed. In this case it was found that the animals which got salt took 38.4 lbs. of food daily; those which got none, 35.9.; or for every 100 lbs. of live weight, the first took 3.2 lbs., the second 3.1 lbs., or rather less. 100 lbs. of food consumed with salt gave an increase of 6.8 lbs. of live weight; and without salt, of 7.2 lbs.

Little difference is, therefore observable between the results of the two cases; but, such as it is, it is unfavorable to salt, a somewhat larger quantity of food being necessary to produce a given increase with salt than without it. Boussingault himself remarks that the difference was so trifling that it might be disregarded; but he says also that there was a marked difference in the general appearance of the animals. Those which got salt had a lively appearance, their eyes bright, and their skin smooth, soft, and shining; while those which got no salt were dull and inactive, and their coats rough and staring; and this difference was so great that it could not escape the observation of the most cursory observer, and there could be no doubt that the former would have brought a higher price in the market. A series of experiments made by a German observer (Farthmann) on sheep lead to an opposite conclusion. He took thirty sheep and divided them into three lots. They all got daily 1 lb. hay, 3 lb. straw, and 3 lb. potatoes; and during the latter part of the experiment,  $1\frac{1}{4}$  lb. of beans were added. One lot got no salt, but the other two were supplied with it in different quantities. The result is shown in this table:—

|                                        | Average gain in weight<br>per sheep. |
|----------------------------------------|--------------------------------------|
| No salt, .....                         | 13.1 lb.                             |
| $\frac{1}{4}$ ounce of salt daily..... | 16.9 "                               |
| $\frac{1}{2}$ " " ".....               | 17.7 "                               |

Here the difference is marked, but the effect appears to be very irregular, for some of the sheep which got no salt had actually lost weight to the extent of 1 or 2 lb. Some experiments of Sprengel's also tend to show that salt promotes the production of wool: for of two lots of sheep which got 3 lb. of potatoes and  $4\frac{1}{2}$  lb. to 5 lb. of rye straw daily, those which got salt yielded 1 lb.  $11\frac{1}{2}$  oz. of wool more than the others. It is worthy of notice that in both these experiments the food contained a very small quantity of salt, amounting, in Farthmann's experiment, to about 41 grains, and in Sprengel's to 8½ grains daily, quantities which are probably insufficient to maintain the functions in a state of health.

An interesting series of experiments has recently been made by Lehmanu on the quantity of salt consumed by draught horses. The animals on which he experimented were doing their daily work, and fed on the mixture of food, which, by actual analysis, were found to contain daily 290.8 grains of salt. Into the manger of each horse was placed a lump of rock-salt weighing 8 or 10 lb., which it was allowed to lick *ad libitum*. The quantity of salt consumed during the first three days was very large, and amounted in the case of one horse to nearly 10 oz. per day: but it rapidly fell, and at the end of six weeks the consumption did not exceed 200 grains per head, and the animal which began by taking so large a quantity of its own

accord entirely abandoned its use. The salt consumed by different horses varied very much, but was always largest in the case of old animals, so much so, that Lehmann remarks that the quantity eaten might almost serve to give an approximate estimate of the age of the animal. It was observed also that when the horses were worked hard, the quantity of salt used invariably diminished. The following table gives his results on this point:—

|                    | Average daily consumption. |            |
|--------------------|----------------------------|------------|
|                    | Light work.                | Hard work. |
| Young horses ..... | 199 grs.                   | 132 grs.   |
| Old horses .....   | 305 "                      | 166 "      |

If we add to these numbers the quantity of salt contained in the food, we may draw the conclusion, that according to the age and work, the total amount of salt required for maintaining the functions of a horse in a state of health varies from 400 to 600 grains daily, and it may be reasonably inferred that if the food contains this quantity, the addition of salt may generally be dispensed with.

*(To be continued in next number.)*

## Agricultural Intelligence.

### Sorghum Sugar.

The Executive Committee of the State Agricultural Society of Illinois, is in session at Springfield. The correspondent of the Chicago *Times* writes that the greatest enthusiasm seems to prevail all over the state in regard to the Sorghum question. There are many growers there, all of whom have met with marked success in its culture the past season, and who will embark more largely in the enterprise another year. The samples of both sugar and syrup there shown would convince the most skeptical of the feasibility of its becoming one of the fixed staples of Illinois.

Among the more prominent of these exhibitors of sugar, I may mention Mr. J. H. Smith, of Quincy, Ill., who presents a sample of a lot of about *one ton*, the largest amount, I am sure, ever made by one man from northern cane. It should be stated that this was made from the African cane and not from the Chinese. Mr. Smith considers this much the best cane for the production of sugar. He states that about seven tenths of the syrup runs to sugar, and that he can make the sugar at five cents per pound and molasses at twenty-five cents per gallon, and realize more profit from an acre of cane than he can from an acre of corn.

A fine (much lighter color and drier) sample of sugar is present from Blymers, Bates & Day, Mansfield, Ohio, I do not know how large a quantity they have produced.

Much interest also attaches to the fine samples

of refined syrup from the refinery of Mr. Corbett, of the *Prairie Farmer*. Everybody is delighted with it, none placing it, for flavor and sweetness, below the golden syrup of commerce. The whole question will receive the attention it deserves at the hands of the Executive Board. I have heard men, prominent in agricultural matters, state to day that every doubt they have heretofore entertained in regard to the profitable production of both sugar and syrup upon our prairies is entirely dispelled by the samples now on exhibition here and the statements accompanying them.

### Advantages of Crushing Oats.

The London Omnibus Company have lately made a report on feeding horses, which discloses some interesting information, not only to farmers, but to every owner of a horse. As a great number of horses are now used in the army for cavalry, artillery and draft purposes, the facts stated are of great value at the present time. The London Company uses no less than 6,000 horses; 3,000 of this number had for their feed bruised oats, and cut hay and straw, and the other 3,000, got whole oats and hay. The allowance accorded the first was, bruised oats, 16lbs.; cut hay, 7½lbs.; cut straw 2½lbs. The allowance accorded to the second was, unbruised oats 18lbs., uncut hay 13lbs. The bruised oats, cut hay and cut straw amounted to 26lbs.; the unbruised oats, etc. to 32lbs. The horse which had bruised oats, with cut hay and straw, and consumed 26lbs. per day, could do the same work, as well, and was kept in as good condition, as the horse which received 32lbs. per day. Here was a saving of 6lbs per day on the feeding of each horse receiving bruised oats, cut hay and straw. The advantage of bruised oats and cut hay over unbruised oats and uncut hay is estimated at 5c. per day on each horse, amounting to upwards of \$300 per day for the company's 6,000 horses.

IMPORTATIONS OF ANIMALS FOR STOCK.—The following resolutions have been adopted by the Board of Agriculture of Lower Canada:—Resolved that, in the opinion of this Board, agriculture would derive great advantages from the importation for many years to come of improved stock of cattle. That, in order to procure the best results, as the most prompt and most general, this Board recommends to all the Agricultural Societies of Lower Canada to appropriate for the period at least of three years an annual sum for the importation of animals of good stock. This Board, in order to facilitate these importations, and to diminish the expense thereof, engages itself to purchase these animals and deliver them to the different societies without other charges than those of purchase and carriage.

## EFFECT OF COLD ON FATTENING ANIMALS.

Dr. Playfair, in the Journal of the Royal Agricultural Society, in speaking of the necessity of warmth to fatten an animal readily, says that to keep up the animal heat, the oxygen of the air unites with that portion of blood which goes to form fat and tissue, and converts it into carbonic acid, water, and ammonia. Where all the vitality of the animal is used to manufacture heat, there is no power left to increase the fat. If we would fatten animals in winter we must give them a summer temperature, by warming the shed and stable they occupy. The air that they breath should be as pure as possible.

## Horticultural.

For the "Agriculturist."

### Dwarf Apple Trees.

On seeing a few remarks in the April number of the *Agriculturist*, made by Mr. Atkins, I would say to him that I believe from his experience, together with mine, that the representations made by the nursery-men in their catalogues and books, that the dwarf apple will bear when it is a small bush, or like the dwarf pear, is only a humbug, and done for the purpose of selling their trees; for, like Mr. Atkins, I have fine model trees eight or ten feet high, and the tops over ten feet in circumference, with limbs branching out from the ground, that have never borne an apple yet. These trees were purchased from the most responsible nurserymen in Rochester, and recommended to bear the second or third year after planting, and are now eight or ten years old.

Mr. Atkins says, if he wanted to make more dwarf trees he would graft them to Keswick Codlin, Hawthorn Dean, and Duchess of Oldenburgh. These trees are early bearers, but they grow as large as any tree, and bear on young standard trees as well as on the Paradise stock. I have late bearing kinds, such as the Northern Spy and St. Lawrence on the Paradise stock, in order to throw them into early bearing, but without effect. I have likewise visited the Rochester nurseries, and found their dwarf apple trees just like my own, and none in bearing except the early bearing kinds as above mentioned. But I am satisfied they are a better stock to graft on than the common standard, as they are more hardy and more fibrous, not forming such huge prongs, running deep in the cold and wet ground. Their branching from the ground is also a self protection to the tree, and will be the cause of it being more hardy; for no fruit tree in this country should be trimmed up and distorted, leaving a long trunk to the merciless extremes of heat and cold of our extreme climate, which will disarrange the sap vessels and cause the tree to become diseased and short-lived.

I now wish to ask for more information respecting the dwarf apple trees, to show if the above statement is not true, that others may not be deceived as to the nature of the trees, as we have been. Any information respecting the nature and habits of the dwarf apple tree, or what treatment will cause them to bear when young and small, will be thankfully received.

R. B. WERDEN.

Picton, Prince Edward County, Jan. 1862.

---

## Cultivation of Plums.

The following observations on Plum culture, written by J. M. Barret, of Canterbury, N. Y., and published in a recent number of the *Horticulturist*, will be acceptable to fruit growers generally.]

So much has been said and written of late upon the Grape question, that I begin to fear that we may forget that other fruits can be successfully raised. I therefore propose to give you my experience in raising Plums, in which I have made a profitable experiment, willing that my fellow readers of the *Horticulturist* may go and do likewise, if they believe the Yankee maxim, that some things may be done as well as others, and that one man can do what another has done *if he tries*.

In 1856, I set out with care what remained of 700 or 800 Plum trees, which had been struck out by contract two years before, and up to that time had refused to thrive. This transplanting revived them, and from that period I date the beginning of my experiment, which, including the present season, makes six years that they have been under treatment. The ground between the Plum trees has been regularly plowed and cultivated for the Raspberry crop, the product of which has paid all expenses, including \$50 per year ground-rent, for two acres and a quarter, and a profit besides. In 1859, I spread under each tree half a peck of common salt.

The black knot upon these Plum trees has appeared regularly every year, and has been cut out clean to the healthy wood in the month of June, say within a fortnight after its first appearance, and while the excrescence was still soft. It is then easily removed without injury to the tree, the wound generally healing over the same season. For the last three years this disease has decreased yearly. The past season I removed the whole from 640 trees in less than half a day. In 1859, these trees began to bear fruit, yielding twenty bushels, which was sold for fifty-five dollars, after paying expenses. In 1860, the crop was nine bushels and one peck, which brought

three dollars a bushel. In 1861, I gathered and marketed seventy-two bushels, for which I received five dollars and twenty cents a bushel, after paying expenses. The total receipts for the three years amount to four hundred and forty-eight dollars and seventy-five cents, after paying all expenses, and amounts to about three times the original outlay, including cost of trees, labour of setting, and transplanting. I know of no business which pays a better profit upon the investment. Only about one-half of my trees have yet borne fruit. Many of them produced from six to twenty Plums the past season. Of course, the production may be expected to increase for many years.

The variety cultivated by me is the free-stone frost Plum, which is the most prolific. The cling-stone is much the finest variety, holds good on the tree two or three weeks later, and brings a higher price in market.

The secret of my success may be summed up as follows:

1. By selecting varieties that are but little troubled by curculio, and that are marked without damage to the fruit; these, being used for preserves, are gathered before they become soft and mellow enough to eat; consequently, they are not injured by transportation to market, and are sure to bring a good price.

2. By careful planting in ground previously prepared and mellowed, and kept so by yearly working.

3. By use of salt as manure.

4. By an unsparing use of the knife upon the black knot in the month of June of each year, instead of waiting until fall or the next spring, or perhaps neglecting it altogether.

In former years the Plum crop of this country was a source of profit to almost every farmer, but the curculio has attacked and destroyed the finer varieties of fruit, and the black knot made such havoc among the blue Plum trees as to discourage its culture. May we not hope to see this fruit again generally cultivated for market purposes.

### Fruits, Flowers and Seeds of the West.

Nebraska is not entirely void of those little comforts that render it a home to us. Many wild fruits are to be found in abundance.—The plum, grape, gooseberry, strawberry and raspberry grow spontaneously all along our little streams and on the borders of woodlands. Gooseberries of an enormous size and fine flavor, that do not mildew and are hardy, give us their yearly crop of wholesome fruits. There are plums growing in some portions of the Territory that are *curculio* proof, and are large, fine and delicious.

But the "Flora" of the Western prairies

and plains is the admiration of all that behold them. There are a great many flowers growing wild of greater beauty and attraction than hundreds now in the flower gardens of the East, that have cost them vast amounts to get them there, while these prairie beauties are left for us to enjoy. They are left because they are not known to eastern botanists and gardeners.

We have a friend who, we understand, has been engaged the past season in collecting many kinds of shrub, flower and creeper seeds of Nebraska, Kansas, Utah, Minnesota, for a nurseryman of Utica, New York, who will be the first to introduce them to the cultivator and amateurs of the East. When once introduced, the catalogues of eastern seed dealers will have more than one new novelty that it did not possess heretofore.—*Nebraska Farmer*.

## The Dairy.

### Dairy Management.

[It is well known that the breed, and particularly the feeding of cows, have a great influence on the amount and character of dairy products, to which we may more fully advert hereafter. In the meanwhile we give our readers some excellent information on the Dairy Management, from the *Irish Agricultural Gazette* of January 4th.—EDS.]

#### BUTTER.

The first essential, in either case, is a proper dairy or milk-house; and when we consider the abominable manner in which milk is frequently kept in dwelling houses, even in sleeping apartments, in barns, where there is no protection against dust from the thatched roof and cob-webbed walls, we cannot feel surprised that there is so much good milk annually wasted in making atrociously bad butter. The milk-house should be sufficiently roomy, and fitted up so that it can be easily kept clean, and perfectly dry. For this purpose, polished stone is the best material; and the immense quantities of marble which are found in many parts of Ireland could be turned to great advantage in this way, whilst, at the same time, shelving of that nature would not be too expensive. Caithness pavement, being hard, dry, and susceptible of a high degree of polish, which is given to it before the stones are shipped, forms also very superior pavement and shelving, and is obtainable at moderate cost. Ventilation is likewise a necessary point in a dairy, and it must be so arranged that the milk-room shall be cool in summer, and yet kept at a sufficiently high temperature during winter, which should never be below 50 degrees F. The

average temperature of Mr. Horsefall's dairy is 42 degrees to 56 degrees; and he is now recognized as a standard authority on many points of dairy management.

Earthenware dishes are much better adapted than wooden ones for holding milk, because the latter require much more labour in keeping them clean, and some dairymaids are apt to be negligent on this point. Cleanliness—extreme cleanliness, in fact—is all-important in dairy management; for the least mustiness in milk-vessels will taint the milk, and injure the butter. The churns must be thoroughly scalded after each churning, and kept clean, sweet, and dry.

Butter is made either solely from cream or from the whole milk; that is, the cream is not separated from the milk, in the latter as in the former case, but both are kept and churned together. There is a difference of opinion as to which mode produces most butter. We would remind those who are not accustomed to the latter method that they must not attempt to churn the *whole milk* while it remains sweet, otherwise their labour will be lost, for it will yield no butter; the whole milk must be kept until it has become sour, when if all other points are equally attended to, as good butter will be produced as from cream alone.

Supposing the cows to be all milked—and this must be thoroughly done, for the last milk which can be drawn from the udder is the richest—then the milk is poured through a milk sieve into the dishes, so as not to be more than two inches in depth; at the same time, 4 to 6 inches is more common. Cream will not rise when there is a considerable depth of milk placed in the dish, and some people do not allow it to exceed one inch. It also rises sooner in warm weather than in cold, and for this reason it must be skimmed sooner when the weather is warmer than usual. In ordinary cases, the cream should be skimmed about 20 to 24 hours after the milk has been put into the dish; in warm weather taking it off somewhat sooner, and allowing it to remain a little longer in cold weather. As the cream is skimmed, it is put into an earthenware jar, the top of which is covered with a piece of muslin, in order to prevent flies or dust getting into the cream, whilst it admits air. As additions of cream are made to that in the jar, the whole should be thoroughly stirred and intermixed together, and the contents should not be allowed to remain longer than three or four days without being churned.

When the whole milk is churned, it is strained, as milked, into milk dishes or coolers; but a greater quantity is put into each dish than is done when the cream is to be taken off. In the north of Ireland, where churning the whole milk is a prevalent practice, the milk is strained into a jar or "crock," successive milkings being added until the jar is full, but avoiding putting in new milk just before churning; that is, suppose the churning takes place in the course of

the forenoon, the morning's milk is not added to the contents of the crock which are to be churned, but put into a fresh crock, and becomes the beginning of another gathering. This system, however, is not so good as keeping each milking by itself, so that the warm and cold milk is not mixed together. The frequency of the churning will partly depend on the weather, but the whole milk ought not to be allowed to remain longer than three days in ordinary cases, or, perhaps, four without being churned; and, in warm weather, it may be churned in two days from the time the first of it was taken from the cows.

In large and even moderate dairies the churns are driven by power, which is preferable to manual labour. Hot water is often added to milk or cream, to bring it up to the proper temperature for churning—say 52 or 53 degrees; but this is not a good practice, and where an increase in the temperature is necessary, it is better to acquire it by putting the churn containing the milk or cream into a tub filled with a sufficient quantity of water to bring the contents to a proper state. During the process of churning, the temperature will rise to 56 or 58 degrees; but it is requisite that attention be paid, so that it may not rise much higher than that point, otherwise the butter will be injured. When whole milk is churned, it will stand, however, a higher temperature than cream. Rapid churning is not desirable, and over churning is equally bad; but the best medium will be found when it takes an hour and a quarter of steady churning in ordinary weather, to produce butter.

There is a difference of opinion as to the mode of handling butter after it is taken from the churn. Some put it into a small, flat tub, and wash the buttermilk out of it by kneading it among clear, cold spring water, the milky water being occasionally poured off, and fresh supplies added, until it ceases to become tinged with milk; others knead and beat it in a clean cloth, which absorbs the buttermilk, and is frequently wrung dry. Until the buttermilk is entirely taken away; whilst a third set of butter makers say that it ought to be worked by means of a wooden skimming dish, and that to work it in any degree by the hand is to spoil it, for the heat and perspiration, which is said to render the butter waxy. Mr. Ballantine's method, as detailed in the prize report in the *Transactions of the Highland Society*, was to extract the milk by working it with the cool hand, but the butter itself was not washed or worked in water. Mr. Dillon Croker, who paid great attention to the management of butter, recommended that, after finishing the churning, the milk should be drawn off by a plug from the bottom of the churn, and replaced by a quantity of pure spring water. A few turns of the wheel is then given, and the water run off; this is to be repeated until the water appears as clean as when it is put into the churn, showing that the milk has been all extracted. A strong

pickle, well strained is now put on the butter and several turns of the paddles given, so that every part will feel the effect, which finishes the operation. If the weather should prove warm, it will be advisable, he considered, to let the butter lie in the churn for a few hours, which will render it firmer than it was when the washing was finished.

The salting process should commence directly after the buttermilk has been all extracted from the butter, and the quantity of salt must be regulated by the purpose for which the butter is intended. When it is to be sold merely powdered, a quarter of an ounce of salt will be a sufficient for a pound of butter. For ordinary keeping purposes, or the London market, it may be cured with half an ounce of salt to the bound of butter, and many add a quarter of an ounce of yellow sugar, and one-eighth of an ounce of powdered nitre. For export to the colonies, or long keeping, more salt is necessary, and as much as one ounce of salt, with a proportionate quantity of sugar, and the foregoing quantity of nitre, will be required. Nitre and sugar are both omitted by many, but these ingredients assist in flavoring and preserving the latter.

The salt used must be of the purest description, free from salts of lime and magnesia which exist in ordinary sea salt. Prof. Johnson recommended the purification of common salt for dairy purposes "by pouring two quarts of boiling water upon one stone or two of salt; stirring the whole well about, now and then, for a couple of hours, and afterwards straining it through a clean cloth. The water which runs through it is a saturated solution of salt, and contains all the impurities, but may be used for common culinary purposes, or may be mixed with the food of cattle. The salt which remains in the cloth is free from the soluble salts of lime and magnesia, and may be hung up in the cloth till it is dry enough to be used for mixing with the butter, or with cheese." The salt must be rendered as fine as possible, which may be done by crushing it with a rolling-pin, and the nitre and sugar well mixed with salt, when these ingredients are used along with it. In salting, the butter is spread out thin in the tub, and the salt, &c., carefully sprinkled over it, and worked in with "the heel of the hand," until the whole is thoroughly intermixed. Some only work in half the salt at first, and then lay the butter aside till next day, when the remainder is added after pouring off any brine which has come from the butter. A great deal of Irish butter is spoilt by over salting.

When the salting process is completed, the butter is packed into "crops"—earthenware jars—or into small casks. The former answers well enough when the butter is intended for home use, but when it is to be sent by rail or steam-boat it should be packed in firkins. These are made of ash and oak, and previous to being filled with butter, they must be first filled with boiling water which will be allowed to remain in them for 20

or 24 hours; they are then rinsed in clean, cold water, and filled with strong, hot pickle, which may remain in them until they are required for use. The firkins are weighed before the butter is put in, and half a being allowed for any additional soakage that may take place, the weight of the firkin is branded upon it. A little fine salt is then sprinkled in the bottom, and the butter packed tightly with a wooden rammer, or with the knuckles, and the greatest attention must be paid to this operation, so that there shall not be any vacant point left, as the air contained in that vacant space, no matter how small, would soon spoil the butter. If the firkin or jar is not filled at one churning, the butter must be covered with pickle, or some salt is sprinkled over it, and a clean cloth pressed close upon it, to keep out the air until the next churning is ready, when the pickle is poured off, or the salt carefully removed with a spoon, and the smooth surface is roughened or raised into furrows, for the purpose of allowing the last packed butter to become perfectly united to the first, without any appearance of seam, which would be the case were this precaution neglected. When the firkin or jar is filled, a little salt is strewn on the surface, and a piece of linen, dipped in strong salt and water, is spread equally over the top, when the cask may be headed, and is then ready for market, to which it should be sent with as little delay as possible.

Butter which has been improperly packed, or otherwise affected by the air, becomes rancid; but this may be cured by beating in water into which from 12 to 15 drops of chloride of lime to the pound of butter have been added. After working it well, leave it lying in the water for two hours, and then wash it in pure cold water, when it will be found to have become sweetened.

#### CHEESE.

There is considerable diversity in the manufacture of this article; so much so that not only is there a marked disunion between the cheesy produced in different districts, but it frequently happens that such is also the case on adjoining farms in the same district. In the latter case, no doubt, whilst the distinction may arise from natural causes, such as the nature of the pasture, and of the breed to which the cows belong; still it is well known that much of the character of cheese arises from the manner in which the milk has been previously treated, and, in the case of skim milk cheese, from the proportion of cream which has been allowed to remain on the milk. Some "goodwives" are notorious for keeping what is called "a good creaming-dish;" that is, they are very particular in removing every particle of cream from the milk, for the purpose of making butter, and the cheese made from such milk is, therefore, of a peculiarly leathery texture. It was an article of this kind which elicited a rather pithy criticism from a half-witted fellow who got a living by running errands about Dunblane, in Scotland. On one occasion, he was

sent to a farm-house where the "creaming-dish" was very vigorously used, and on being set down to a repast being composed of bread, butter, and cheese, he was observed to spread the butter pretty thickly over slices of cheese, muttering all the while, quite loud enough to be heard by the bystanders, "Deil be in their fingers that ever paired ye."

But it appears to be the case that for some unknown reason cheese cannot be successfully made in some parts of the country, and we have found some marked instances of this in Ireland, both on the sown grasses of a five shift course and on the old pastures of the Golden Vale, and that, too, where it had been tried by persons who had been all their lives well acquainted with the process of manufacture as practised in Cheshire and Ayrshire. At the same time, we found excellent cheese made on other farms at no great distance, but certainly where the soil and pasture were somewhat different, showing that there is nothing in the climate at least, as some allege, to prevent cheese making being carried on in Ireland. It has never gained a footing in Ireland, however.

When skimmed milk is set aside for cheese making it must be scalded, but *not* boiled, in order to prevent it from turning sour, which would spoil the cheese. In making sweet milk cheese—that is, when the milk is used without being deprived of the cream—the morning's milk is mixed with that of the preceding evening—supposing there is a sufficient quantity of milk to allow a whole cheese to be made every day—the cream which has gathered on the evening's milk being mixed through the entire quantity, the temperature of the whole being raised to a certain degree by heating a sufficient quantity of milk in a pan set in boiling water, and then pouring this warmed milk into the rest. The temperature to which the milk is raised ranges from 75° to 80°, and even 90°, a higher temperature being requisite in cold than in warm weather. The milk at this stage is all in one tub, and it is at this point that the "rennet" is added. This is prepared from calves' stomachs, which have been salted a year before they are used. These can generally be procured from shopkeepers in the dairy districts; and where cheese is the sole object of manufacture, two "bags," or "vells," as they are sometimes termed, are necessary for the milk of each cow during the season. In some cheese districts, stale rennet is used; in others, as in Cheshire, it is prepared on the day previous to being put into the milk. The Cheshire system is to cut two bits of two or three square inches of the vells or bagskins, and those bits are "put into half a pint of warm water the day before use, along with a teaspoonful of salt, and this infusion suffices for 50 or 60 gallons of milk" (Morton). In Gloucestershire, where stale rennet is used, 6 vells are put to every 2 gallons of brine, and in large dairies a 30 to 40 gallon cask is prepared at once. The infusion is considered to improve with age, that is, if it is not further di-

luted by the addition of more brine. Stale rennet is also used in Ayrshire in the manufacture of Dunlop cheese, and in that which is made according to the Cheddar system, a tablespoonful of the rennet being added to every 20 gallons of milk. It is at this stage also that annatto is added for the purpose of colouring the cheese—a practice which, we think, ought to be given up; for it is only a mere fancy, and does not improve the quality of the cheese in any degree.

The time requisite for coagulation varies according to the temperature of the milk when the rennet is put into it. Where the temperature ranges from 75 to 80 degrees, the curd will usually take an hour to form; but where the temperature is from 85 to 90 degrees, it may only require half the time, or even less. Too rapid coagulation is not desirable.

The subsequent steps in the manufacture of Cheshire cheese are described in the following manner in Morton's excellent little work, the *The Hand book of Dairy Husbandry*. After the curd is fully formed,

"It is then cut slowly with a wire curd-breaker, and the curd sinking, the whey is baled out; the curd is collected and squeezed, both by hand and the direct pressure of a weight above a board placed upon it; and the last of the whey being removed, it is lifted either into a basket or into one of the Cheshire cheese vats ('thrusting tubs') pierced with holes for the further escape of the fluid, the lower part being a wooden cylindrical vat, and the upper a tinued cylinder slipping into it, as the curd on pressure sinks. After a certain pressure in this form, the curd is removed and cut, and broken by hand or a curd mill, and from 1 to 2 lbs. of fine salt is scattered over it, according to the weight of the cheese; about 1 lb. to every 40 lbs. of cheese is a common quantity. The whole curd being then re-broken, is refilled into the vat, in which a cheese cloth has previously been placed. It is then put gradually under pressure [in a lever cheese press,] which after the second or third day amounts to nearly a ton weight upon each cheese.

"Every day the cheese is turned, and wrapped in fresh cloths, and on the seventh or eighth day of this treatment, or as soon as dry, it is removed to the loft, and there swathed around with strong ginning, and placed on a bench. By-and-by it is laid, still swathed as before, on a layer of straw on the floor of the room, and there it lies till from ten weeks to four months old, when it is ready for sale."

It is of the greatest importance that the curd be freed entirely from the whey; for if any whey is left, the cheese is apt to swell and burst. For this reason, in some dairies it is the practice, on the first day when the cheese is put under the press, to thrust skewers into it through the holes in the cheese-vats, in order that the whey may more readily drain off through the holes pierced with skewers. The whey is scalded and given to pigs.

**VARNISHING CHEESE.**—A writer in the *Dairy Farmer* states that it is the practice of some dairy-men to coat each cheese thinly with varnish made from shellac dissolved in alcohol, when about to ship to market. It is said to improve the appearance of the cheese and to keep it from losing weight and gathering mold. We cannot say as to the value of its recommendation.

## Domestic.

### Housekeepers' Recipes.

**To Make White Indian Meal Cakes.**—I read one of your receipts for making "Indian cakes" to my wife, from one of your late numbers, and we had a laugh over it. Annexed is her mode of making them: To enough white meal for breakfast add sufficient salt, then mix entirely with boiling water, to the consistency of a stiff batter, and bake immediately on a hot griddle, well greased—the batter to be put on the griddle with a large spoon, one spoonful for each cake. No mixture of Indian meal can exceed these cakes in delicacy of flavor. This is the way we make them down in Delaware.—*Germantown Telegraph.*

**For Killing Rats.**—Mix some unslacked lime with corn meal, and place it where the rats may accidentally find it. They will soon become very thirsty, and upon drinking water, the lime slacks and swells the rat till it kills him. In the Bahama Isles, sponge is fried and placed in in their way; they eat it, drink, swell, burst and die. Lime and meal should be, of the first one part and meal two parts, well mixed together and dry.

**Starch.**—There is no better way for making nice starch for shirt bosoms, than to boil it thoroughly after mixing, adding a little fine salt and a few shavings of a star or spermaceti candle; the star or pressed candle is quite as good as sperm. Let the starch boil at least ten minutes, and it will give a gloss, if neatly ironed, fully satisfactory.

**Mince Pie without Meat.**—Four soda crackers, four cups of water, two cups of sugar, one cup of butter, one cup of chopped raisins, half a cup of vinegar, one lemon, grated citron, nutmeg, allspice, cloves, cinnamon, etc.

**To Broil a Fowl.**—Split the fowl down the back, season it very well with pepper, and put it on the gridiron, with the inner part next the fire, and allow the fowl to remain until it is nearly half done; then turn it, taking great care that it does not burn. Broil it of a fine brown. A duck may be broiled in the same way. If the fowl is very large, half roast it, and then cut it into quarters and finish it on the gridiron.

**Indian Arrow Root.**—To a quart of meal, pour boiling water, stirring constantly until a

thick batter; let it cool; while warm, add a small teacup of butter, a teaspoonful of salt, and a tablespoonful of yeast, with two well-beaten eggs; set it on a warm place for two hours, then stir it smooth, and bake in small cakes on a griddle: when one side is rich brown turn the other; lay them singly on a hot dish, and serve. These may be made without the yeast, and baked as soon as mixed.

**Muffins.**—Mix a quart of wheat flower smoothly with a pint and a half of lukewarm milk, half a teacup of yeast, a couple of beaten eggs, a teaspoonful of salt, a couple of table-spoonful of lukewarm melted butter. Set the batter in a warm place to rise. When light, butter your muffin cups, turn in the mixture, and bake the muffins a light brown.

**Cleaning Papered Walls.**—The prudent housewife who, on account of "hard times," has decided not to re-paper the sitting-room, as desirable, will find the old paper very much improve in appearance by simply rubbing it well with a flannel cloth dipped in oatmeal.

**To Clean Knives.**—One of the best substances for cleaning knives and forks is charcoal, reduced to a fine powder, and applied in the same manner as brick-dust is used. This is a recent and valuable discovery.

### Preparation of Chicory.

**EDITORS OF THE AGRICULTURIST.**—Can you or any of your subscribers inform us of the best way to prepare chicory for mixing with coffee? We grow it, and are fond of it, but think we have not the proper method of preparing it for use.

NIAGARA, Jan. 1862.

W. C.

[We are not aware that there is any other mode of preparing chicory for use as a substitute for coffee, than that of first drying, and then roasting and grinding the root. After the roots have been cleaned, and sliced in the thick parts, they may be placed in an oven, after the bread has been removed, and remain there till they cool. If one such baking should not dry them sufficiently the operation may be repeated. The Rev. W. L. Rham, in his Dictionary of the Farm, in speaking of the cultivation and preparation of chicory in Belgium and Germany as an article of commerce, says:—

"In September the leaves should be finally gathered and the roots taken up, which may be done with a common potato fork. They are then cleaned by scraping and washing, split about two or three inches long. These pieces

are dried by means of a slow oven or a kiln. Some nicety is required in drying, to prevent the root from being scorched, and to keep the proper flavor. In this state it is sold to the merchants, packed in bags. It is afterwards cut or chopped into small pieces, and roasted exactly as coffee, ground in a mill, and packed in papers in pounds and half pounds for retail sale. When coffee, as well as all colonial produce, became too dear for the laboring classes in France and Germany, chicory was almost universally used as the best substitute, and the taste is by many thought so grateful, that they prefer the coffee with which a fourth or a fifth part of chicory has been mixed."

We have seen it stated that chicory is apt to produce injurious effects upon the constitution when used too freely. Should any of our correspondents know a better way of preparing it for use than the above, we shall be happy to hear from them.—EDITORS AGRICULTURIST.]

## The Poultry Yard.

### Profitable Poultry Keeping.

*Fowls and their Breeds.*—A poultry keeper, in the *Journal of Horticulture*, places in order of profitable merit different fowls, in the following order:—

1. *The Speckled Dorking.*—Good layers, setters, and nurses; chickens come early to profit; preferred by dealer.

2. *The White Dorking.*—Flesh of these chickens a better color than the speckled.

3. *The Hamburg Everlasting Layers.*—Lay from 200 to 250 eggs yearly; do not sit well; flesh good.

4. *The Game.*—Flesh and eggs excellent; but rear with difficulty.

5. *The Cochins.*—Best for confined places; rear early; eggs excellent, sits true; good nurses; flesh not very good.

6. *The Spanish.*—Shy layers, poor sitters; bad nurses; eggs large and poorish; do not rear well. Poultry should be kept perfectly clean, have access to chalk, and a dust heap carefully kept dry for them to busk in.

## Poultry.

We are indebted to the *Irish Farmer's Gazette* for the following remarks, gathered from different sources. In the old country fowls are generally prepared for table in the natural way, but French feeders prefer a system of forced feeding, the details of which may be gathered from the following description given in a recent number of the *Journal of Agriculture*:—

"A sketch of the mode in which the La Fleche virgin cocks and poulards are fattened will convey a good notion of the manner in which this process is frequently managed in France. It is undertaken chiefly by country dealers and small cultivators, called *poulaillers*, and although attended with a good deal of trouble and expense, they manage to realise fair profits—some of them even small fortunes. The individuals buy up, from the markets and their neighbours, the young *coqs vierges* and pullets, which they name *gêmines*, that appear to be finest, and best fitted for fattening. About the age of seven or eight months, they are considered best adapted to the purpose. From fifty to a hundred are subjected to the process at one time, and it generally commences in October. In the apartment where it takes place, a series of boxes or frames, formed of rough timber, are placed on the floor—one portion of the covering fixed, the other movable—for the purpose of putting in and taking out the fowls. The dimensions of these boxes vary, but they should never contain more than six birds, and the space should be such as to accommodate each comfortably, without permitting it to move about. No light is admitted from without, and very little air. In order to accustom the fowls gradually to the dietary regimen and seclusion to which they are to be subjected, for the first eight days they are enclosed in a place only partially darkened, and fed on a somewhat thin paste, composed of meal, with a mixture of a third or a half of bran, and they are allowed to eat and drink at pleasure. The paste cakes, or *patons*, on which they are to be fattened, are composed, the one-half of buckwheat meal, a third of barley meal, a sixth of oatmeal, the coarse bran being removed. Every day this substance is steeped in milk in the quantity necessary for two meals. Some add to the paste a little lard, particularly when the treatment is drawing to a close. Being neither too hard nor soft, it is easily rolled in small cakes or *patons* nearly in the form of an olive, and of a size adapted to the throat of the fowls.

The times of feeding require to be strictly attended to, and the poultryman or feeder, aided by the light of a lamp, takes three fowls at once, ties them altogether by the feet, and rests them on his knees. He then makes them swallow a spoonful of water or whey (although this

is occasionally dispensed with), inserts a paton in the beak of each, and gently slips it downwards by the pressure of his two fore-fingers and thumb, rubbing his hand along the neck till the food reaches its destination: this prevents its being rejected. The time required for this in each case affords sufficient leisure for deglutition in the others. During the first few days only a small number of patons are given, but they are gradually increased till each dose consists of a dozen or fifteen. They are dipped in water before being administered, in order that they may be more easily swallowed. By this process some fowls are fattened in six weeks, others take two months; the time depends on the constitution of the animal and its degree of strength. Some cannot be brought to the desired plumpness without risk, and in such cases the feeding must be interrupted or modified, as the occasion seems to demand. It is calculated that some fowls consume 20 litres of meal, others one-half more. Two feeds must be regularly given in the twenty-four hours, and the diet indicated must never be altered in its composition. A curious feature in the process is, that the feeding-house must never be cleaned, the fowls have no litter under them, and their dung is never removed. The highly azotised emanations which prevail in the feeding-house are considered necessary to assist the fattening process, although they are disagreeable to the attendants, and not seldom injurious to their health. The fowls are never subjected to any mutilation, as is the case with capons, and often with fowls fattened in other ways. The finer specimens of poulardes attain a weight of upwards of 8 lb, the cocks 13 lb., and these weights are sometimes exceeded."

Another mode of forced feeding consists in

"Causing the fowls to swallow, by means of a funnel inserted into the mouth, farinaceous substances in a liquid state. This latter method, named *entonnage*, is so simple and rapid, that it is thought likely to be adopted in preference to any other. The filler or funnel, made of white iron, should be of sufficient size to hold one meal, having a ring below the rim externally for receiving the forefinger and thumb, and the orifice at the lower extremity cut aslant, the edges surrounded with a thin coating of india-rubber, to prevent injury to the walls of the throat. The beverage, which by this means is to be introduced, consists of barley meal (not bruised barley), mixed up without knots in equal parts of milk and water. When all is ready, the fowl is seized by the wings near the shoulder, the head held forward between the knees and grasped by the left hand, while the right holds the funnel, opens the beak, introduces the instrument into the gullet, and the proper quantity of the mixture is poured in. The quantity of the latter should be about the eighth part of a litre, but only half that quantity is given during the first three days. This dose must be given regularly three times in the

four-and-twenty hours, at intervals of eight hours. The boxes or frames containing the fowls should be placed in a stable or other temperate place, protected from currents of air, and they should be littered with straw, the litter frequently renewed, and every impurity removed, unlike the practice followed with the *La Fleche* pullets. The duration of this treatment is from fifteen to twenty days; if it fails to be successful within that time, the subjects should be withdrawn and otherwise disposed of."

Alluding to the insipidity of the flesh of poultry as an article of food, and which we endeavour to correct by eating it along with ham or tongue, the writer of the article in the *Journal of Agriculture* suggests the possibility of imparting different degrees and kinds of flavour to it by mingling aromatic substances with the usual farinaceous food, the forcing system of feeding presenting the means of accomplishing this end. He reasons from the fact that the nature of the food has an effect on the flesh of animals—thus, "that of the capercaille has the scent of the fir shoots on which the bird feeds; hares inhabiting low wooded regions have less flavour than such as live on mountains. Domestic rabbits are always insipid when compared with wild ones. Birds feeding on certain berries—those, for example, of the juniper—acquire the perfume of their principal food." The flesh of grouse, also, he might have added, has a strong flavour of heather shoots. "Flavoured berries, such as the juniper, the aromatic buds of trees, tops of labiate plants, such as thyme, lavender, odoriferous barks, &c., would form the materials to work with. They would not require to be used but towards the close of the period of fattening, as a short treatment would be sufficient to perfume, at our wish, the whole flesh of the animal. In this way the value of our common fowls might be greatly increased, and they might be brought to equal, and even surpass, many kinds of game." The suggestion is well worth being put to the test of careful practical experiment.

The exhibition of fowls at poultry shows having now become a subject of general interest, we shall be doing young exhibitors a service by transcribing the following useful remarks on this subject from the poultry department of the *Journal of Horticulture* (Nov. 19, 1861):—

"Fowls, to be successful, must be sent in high condition; but even in those classes where weight is an essential, mere fat will not do—large frame-work is necessary. Judges are not guided by mere weight, but the size of the fowl is ascertained and tested by measurement. Excessive fat, so far from being desirable, is a great disadvantage. Fowls suffering from it are necessarily dull and sleepy, they get into the corner of a cage, whence they will hardly allow themselves to be moved, and are spiritless and unattractive. The greatest amount of weight must be attained that is consistent with exer-

cise and hard condition. Beauty of plumage is a great help to success, and this cannot exist with much fat, as its tendency is to loosen the feathers and make them hollow. Fowls should be sent to a show with clean plumage, and those that should be white and are not white should be washed to make them so. Soap and water may be easily and safely used with a flannel; and if the birds are afterwards put in a straw basket with soft straw, and placed before a good fire, they soon become dry. All fowls should also be sent to a show with clean legs. Even where the birds shown do not belong to a breed of which feather is the principal merit, it is desirable to choose those that match as nearly as possible; and in every breed it must be recollected that positive similarity of comb and colour are imperatively necessary to constitute a competing hen in *any* class.

"We advise sending fowls away early to a show. They get more care in unpacking, and they look better before the judges, from having had more time to recover the effects of packing and the journey. It is, besides, due to the members of any committee who undertake the task of unpacking. There is no reason why they should be kept at their unpleasant work all night. It is also far better, where they have a long journey before them, that fowls should travel at night. Those who manage to a nicety are sometimes too late, and at others they arrive after the judges have commenced their work. One is almost as bad as the other. With regard to the food they should have before they start, it should be of a light character. They have no opportunity in their baskets of finding stones to assist in digestion, and for that reason we object to whole corn. We believe sopped bread to be the best thing they can have, and in very severe weather it is a wise precaution to give them a part of their meal steeped in strong beer."

"All baskets should be round, to prevent any feathers from being broken. There is no angle in such a one for a bird to get into to escape from beating, or to crouch to roost. If it is in motion, the tail follows round, and the feathers are not injured. The basket should be covered with double canvas. It should be large enough to allow all the birds to sit down, and high enough to allow the cock to stand upright without injury to comb or top-knot."

(Concluded in next number.)

## The Apiary.

### On the Management of Bees.

To the Editor of the Canadian Agriculturist.

SIR,—In the October number of your valuable journal I noticed the following enquiries by "Apriarian," addressed to the bee-keeping community, for information as to the results of their

experience in reference to the most profitable system, stating the average yield of honey, cost of stocks or swarms, the best time to stock an apiary, and any other particulars that might be useful? I have been looking for the requested information in answer to those enquiries, in the subsequent numbers of your publication, as an interchange of sentiment upon the practice of this pursuit, would have been acceptable to myself and, no doubt, to many others of your subscribers, especially from those apianians who have made it a special business, but have not yet met with it. In the absence of such information, I here submit a brief statement of part of my experience, in connection with particulars from other sources. But, from the limits of a communication of this sort, much of the details of operations in manipulating with the bees is necessarily omitted.

Having taken much interest in the natural history and practical management of this wonderful insect for the past twenty years, and keeping a limited number of stocks, I conceived this insect evidently intended for domestication, as much so as any other stock of the farm, its instincts and habits being devised in reference to the benefit of man.

This branch of rural industry is in a very low state, from the small amount of encouragement given by the different local agricultural societies in Canada West, in connection with the large number of failures,—by which bee-keepers have had to renew their stock every few years,—arising from defective management, and too often no management, excepting, of course, the hiving of a swarm and placing it upon the stand, and leaving the subsequent results to luck. The absurdity of a corresponding amount of management in connection with other crops, would be easily seen, and failure anticipated. This low state of the industry has given rise to an unfavorable impression in regard to its profitability and importance, as a natural resource of the country. But a land flowing with milk is inseparably connected with a flow of honey. And if the practical knowledge and attention be given, that the present state of improved bee-management requires, it can be made a profitable business. On the other hand, a deceptive or too sanguine an impression may be produced, from the perusal of those accounts of large profits inserted in many of the published papers, perhaps the results of one year in ten.

The average yield of honey in one locality will not be a reliable criterion for an expected result in another, as different seasons, situation, and the strength of the stock, materially affect the amount of the returns. In the absence of a record of profits, I should judge that from 30 to 50 per cent. on the capital invested in honey would be a safe estimate, leaving a limited number of young stocks, to offset expenses of hives, stands, &c. The prospective profits of the lo-

cality, in which your correspondent resides, will be best judged of, from a view of the surrounding vegetation. White clover, buckwheat, linden, raspberry, the orchards, &c., are the chief sources from which honey is obtained in this country. But white clover takes precedence of all other plants, for its superiority in quantity and quality, often denominated *Fine Canada*.

The growth, maturity, and harvesting of all crops in Canada, is confined to a limited period, and the harvest of honey is not an exception. Consequently, the strength of the stocks should be promoted in advance, by every means within the power of the apiarian, so as to meet the required demand of labour, for a successful improvement of the short time allotted for an efficient gathering of not only an abundance but often a superabundance of the honey, that may be secreted by plants in blossom. For its duration upon the blossoms may prove uncertain. The pasture of bees, is not like pasture of other stock, what is left by cattle to-day can be eaten the next, or the next week, but a storm of rain or a few days of wet weather, will wash the greatest abundance from the blossoms, or a cold spell of weather or drought may check the plentiful secretion for that season. It is obvious from this reasoning, if correct, that *strong stocks*, at the commencement of the season, in this climate, are *the foundation of certain success*, other circumstances being equal, as it is only those stocks, in ordinary seasons, that will realize a surplus of honey, over the quantity required to keep them over winter; and in a season of scarcity, weak stocks must perish, if not previously fed, taken up, or united with other stock. Therefore, assuming my stocks to be strong, at the commencement of the honey and swarming season, I endeavour to keep them so, by limiting the swarms, and returning them to the old stocks, or if movable comb-hives are in use, remove the remainder of queen's cells, in excess of the number of swarms permitted to leave. This hive is an improvement upon the chamber-box, barhives, and a legion of worthless patents, as it gives the apiarian control and power of inspecting the interior, and the past seasons's trial by myself will justify their future use. This mode of increase of stocks is much at variance with the practice of a large number of beekeepers throughout the country. The advantages over the old system are unquestionable, whatever merits other methods may possess, as the loss and waste of a valuable swarm, brood, and bee-bread, with the labour and time in accumulating this wasted product committed to the brimstone pit are *saved*, and are properly directed in the most profitable way, when the increase must be saved or lost. And it will prove ultimately a better guarantee of profitable increase than where more swarms, that is to say, all the first and consequently the best swarms, are allowed to leave without reducing the old stock to become a prey to the moth.

The best time to stock an apiary, is the last of winter or early spring. The operation at this time is attended with the least loss of bees, and any reasonable enhancement of price over the fall stock, will be fully compensated for in the avoidance of care and risk of wintering; although bees can be removed at any seasons of the year, and successfully when swarming, and artificial swarms are the better for being removed some distance. The price of stock will average four dollars, in this section of the country, in common boxhives. Some practical experience in purchasing, is necessary at any season of the year. The common method of judging by the weight of the skip, is not always a safe guide, as old stocks are much heavier in proportion to their contents, and many queenless hives will prove quite heavy.

Some care and attention are requisite in wintering bees, more from the length than the severity of the winter, in order to counteract the accumulation of moisture, generated in all wooden hives, by the breath and heat of the bees becoming frozen, without direct or upright ventilation, but this is in some measure a necessary evil. This is the reason that the common boxhive, placed upon blocks or pins, is so successful, exposed as it is, in many instances, to every vicissitude of the weather. The cold, dry air, and driving winds, dry up the moisture in some measure, but at the expense of the vitality and animal heat of the bees, and extra consumption of food. The evils of this unmerciful exposure of bees, to the severity of a Canadian winter, are increased by the sudden changes of temperature, as a sudden change from a thaw to severe freezing, before the inside becomes dry, will often prove fatal. But, as protection and properly regulated ventilation becomes better understood, this old system will gradually disappear.

Straw hives are better adapted to wintering bees, than wood, as this material is a non-conductor, consequently warmer in winter and cooler in summer, and will absorb and evaporate moisture, and when combined with external protection, either of the same material or wood, will obviate the necessity of direct upright ventilation. But where movable comb-frames and surplus honey boxes are the system, the straw cannot be worked into the proper shape, without being combined with wood. And those complicated arrangements for ventilation can never be adjusted to the sudden changes of the weather by ordinary beekeepers.

There are some objections to straw, as affording a harbour for the moth, but the depredations of this enemy of the bee are better prevented by other means than the adoption of any material of which the hive is constructed, as they will enter any hive that was ever invented, if not prevented by the bees themselves. And honey boxes are the best in every respect for the deposit of surplus honey, both for its security of

transport and convenience of keeping, and a sure guarantee of its purity, devoid of beebread and broodecomb, as the bee store it for themselves, and not for the owner. Whereas hive honey is more or less intermixed with beebread and broodecomb, and the separation cannot be effected in all of it without straining one through the other.

The scarcity of honey has given rise to heavy importations of Cuban, and other West India honey, much of it unfit for table consumption, the best often repacked in kegs, and sold as strained Canadian honey, but box honey requires no warrantee for its purity, and the comb will not exceed one-third of an ounce to the pound. A public revenue derived from this source, as compared with the present public expenditure, through importations, or even a supply equivalent to the demand for home consumption, appears somewhat distant, and will remain so until a corresponding interest is awakened in this branch of rural economy.

The importance attached to this pursuit in Germany, where it is followed as a profitable employment by a large number of its population, and the interest evinced by a large portion of the clergy, as practical aparians, aided by several publications devoted to this and its kindred subjects, have produced corresponding public results, as a few figures here, taken from Longstroth, furnished by Wagner from the statistical tables of Hanover, will show.

The average annual production of wax, in the province of Lunenburg, is 300,000 lbs., and assuming one pound of wax for each hive, we have that number taken up, and computing the whole number, with every allowance for casualties, the lowest estimate would be 600,000 stocks, giving 141 to each square mile, to secure the results in the tables, and this district is so barren that it has been called the Arabia of Germany. And according to Etül, page 339, Bohemia contained 160,000 stocks in 1853, and from a careful estimate, he thinks the country would support four times that number,—the kingdom contains 20,200 square miles. The official reports of Denmark show the export of wax to be from that country, 118,379 lbs. In 1857, the official estimates returned 58,964 stocks for the kingdom of Wirtemberg. And in the same year the yield of honey and wax, in the empire of Austria, was estimated at seven millions of dollars.

As there is unquestionably a lack of information and a degree of uncertainty existing in the minds of a large number of bee-keepers, as to the best method and the probable profits of bee-keeping, it would tend much to the removal of those apparent difficulties, if the different systems were made public, through the columns of your journal.

Respectfully,

JAS. HESLOP.

West Flamboro', Jan. 5th, 1862.

## Veterinary.

### Warts on Cattle.

MR. EDITOR:—Will you please inform me through the columns of the *Farmer* what is the most effective cure for warts on cattle? If you will you will greatly oblige G. C. E.

NOTE. There are several modes of curing warts. Nitric acid diluted with water, applied occasionally, has been successfully used. Chloride of zinc made into a paste with an equal amount of flour, and applied, will act as a caustic and destroy them. A tincture of iodine applied two or three times a week has been known to destroy them. All these things act as caustic more or less strong, which destroys the vitality of the wart, and it is then thrown off as dead matter.—Ed.

We cut the above from an exchange paper. Warts consist in a morbidly increased growth of the outer skin. They generally originate on young animals, and are supposed to be associated with that state of the system when the tissues are in a growing state, as they usually appear during the period of growth, and disappear as age advances. Epidermic warts, when seen in the horse, are found to occupy various situations, as on the nose, eyelids, ears, between the hind legs, or sheath, and under the abdomen. When occurring in cattle, they are chiefly confined to the inferior parts of the abdomen, teats, dewlap, or about the head.

*Treatment.*—The easiest and quickest method of getting rid of warts, when extending over a large surface, is to remove as much as possible with the knife, and apply a hot iron to stop the bleeding, or tie the blood-vessels, and afterwards dress cautiously with arsenical ointment, at intervals of several days. When presenting a well defined neck they may be removed by tying tightly around them a piece of waxed whip-cord; this cuts off all nutrition, and as a consequence they drop off. Calomel is also useful in removing these excrescences.

### The Cattle Disease in Montgomeryshire, Wales.

[REPORT OF PROFESSOR SIMONDS.]

Royal Veterinary College.

In continuation of my former report on the outbreak of a destructive disease among the cattle belonging principally to Mr. Harvey

Jones' tenants in the parish of Llandinam, Montgomeryshire, I have to speak more fully of the nature of the affection, and the causes which produced it; as also of the means which were adopted to arrest its progress, together with the result. In the previous report it was stated that upwards of fifty animals, of various ages, had died up to the time of my visit, and that others were being attacked almost daily. For the first few days after my investigation, the disease continued to prevail with unabated fatality, but it then ceased, and no more cases have since occurred. This sudden disappearance of the affection I believe to be entirely due to the preventive measures which were adopted, and I am warranted in giving this opinion, because all the local causes were still existing.

*Causes.*—Under this head we must class the kind of weather which prevailed during the existence of the disease, the nature of the soil, the character of the food, and the management pursued towards the animals.

The cases occurred principally during October—a month remarkable for its humidity and warmth. The state of atmosphere which then prevailed was accompanied with heavy fogs, and particularly in the district in question. The fogs often hung over the fields excepting for an hour or two throughout the entire day, and were so dense as frequently to hide the animals from observation, although but a few yards distant. Constant exposure to weather of this kind would of itself prove detrimental to health, by impeding the process of respiration, and also the decarbonization of the blood; but besides this it would have an indirect effect on the animal economy no less injurious.

Speaking in general terms of the entire parish, it may be said to have a character of soil described as a clayey loam overlying slate shale. The soil is necessarily very retentive of moisture, and as much more rain had fallen in the district than, as may be said by way of contrast, had done in the vicinity of London or elsewhere, so the land was more than ordinarily wet. I was particularly struck with this, for many of the roads leading to different farms were literally mid-leg deep in mud, and perfectly impassable except on horseback.

The warmth of the atmosphere necessarily induced under such circumstances an abundant growth of grass, and it was stated, in answer to my inquiries, that more keep existed in the pastures than was often to be found in the month of June. The grass however produced under these circumstances would of necessity be not only surcharged with moisture, but proportionally deficient both in albuminous and other proximate principles which are imperatively necessary for the making of pure and healthy blood. Hence

we have another powerful cause in the food itself in inducing the disease.

The abundance of grass likewise led the proprietors of the cattle to leave the animals out night and day without any other provender, with a view of saving their winter keep.

These several things being combined brought about a state of the blood by which it was unfitted for the purposes of life, and as an immediate consequence, local hæmastasia resulted—in other words, the contaminated blood became partially stagnant in the vessels. Sometimes this stagnation took place in one part of the system and sometimes in another. The affected structures became swollen, hard, and painful. The head and throat were the principal seat of the local symptoms, but occasionally the fore or the hind extremities would be attacked. Nor were the external organs exempt, as the lungs were now and then primarily affected.

The duration of the malady varied a little, but was rarely longer than 24 hours; while many of the animals, apparently unaffected in the morning, were dead before night.

In several respects the local symptoms were closely allied to those seen in hæmatosepsis, "black leg," but no gaseous matters were evolved into the cellular tissue, as is the case in that malady. Cattle also of all ages were its victims, and that without respect to their being milking or fattening animals, or store stock.

It was not to be expected that curative means would be of much avail in such a disease, and therefore I learned, without surprise, that little or no advantage had resulted from their application. A case occurring while I was staying with Mr. Powell, Mr. Jones's agent, and the chief occupier in the parish, afforded me the opportunity of giving trial to curative measures, but without much relief, as the animal died in about twenty-eight hours from the time of the attack.

*Preventives.*—It was self-evident that benefit could only result from the application of prophylactics, and especially from removing the causes of the disease to as great extent as possible. With this view I ordered that the animals should no longer be kept in the pastures at night, but be brought into the yards and fed on hay, hay chaff, and bran, and also crushed corn. It appeared to me to be a matter of minor importance what kind of corn was given, and therefore this varied in different instances according to the convenience of the occupier. The chief thing was to limit the amount of succulent diet, and to substitute food rich in the elements of blood. Instructions were also given for the animals to be kept entirely in the sheds and yards on foggy, but especially on wet days.

Besides this alteration in the diet, location, and management of the animals, orders were

given for each to take of nitrate of potash in powder in a bran mash every other night, from two to four drachms, varying according to its age and condition. These doses to be given to the extent of about six or eight in number.

In a few instances, as in Mr. Powell's case, who had been the greatest sufferer, I directed that an aperient combined with a diffusible stimulant should be administered at the commencement of the preventive treatment, which was to consist of sulphate of magnesia, half a pound; compound solution of aloes, from two to three ounces; compound tincture of gentian in the same quantities, and two drachms of powdered ginger. The whole to be given in some well boiled gruel.

As previously stated, these measures at once proved most effective for good, by entirely putting a stop to the further progress of the malady.

In concluding this report, I may remark that these cases possess an especial interest to the pathologist as tending to prove the necessity of giving greater heed to the state of the fluids in many affections of the solids than has hitherto been done, and also in showing that some of the most destructive maladies occurring among herbivorous animals depend immediately for their production on the quantity and quality of their food, the management which is pursued towards them, and the nature of the soil they inhabit.

They also prove to the practical agriculturist that very often the simplest means, when rightly directed and founded upon a scientific inquiry, will suffice to arrest the most fatal disease which may be raging among flocks or herds.

### Miscellaneous.

**THE DOMESTIC TYRANT.**—It is to me a thoroughly disgusting sight to see, as we sometimes do, the wife and children of a family kept in constant terror of the bashaw at the head of the house, and ever on the watch to yield in every petty manner to his whims and fancies. Sometimes, where he is a hard-wrought and anxious man, whose hard work earns his children's bread, and whose life is the sole stay it is needful that he should be deferred to in many things, lest the over-tasked brain, and over-strained nervous system should break down or grow unequal to the task. But I am not thinking of such cases. I mean cases in which the head of the family is a great fat, bullying, selfish, scoundrel; who devours sullenly the choice dishes at dinner, and walks into all the fruit or dessert, while his wife looks on in silence, and the awe-stricken children dare not hint that they would like a little of what the brutal hound is devouring. I mean cases in which the contempt-

ible dog is extremely well-dressed, while his wife and children's attire is thin and bare; in which he liberally tosses about his money in the billiard room, and goes off in autumn for a tour on the continent by himself, leaving them to the joyless routine of their unvaried life. It is sad to see the sudden hush that falls upon the little things when he enters the house: how their sports are cut short, and they try to steal away from the room. Would that I were the Emperor of Russia, and such a man my subject! Should not he taste the knot? Should not I make him howl? That would be his suitable punishment; for he will never feel what worthier mortals would regard as the heaviest penalty by far, the utter absence of confidence or real affection between him and his children when they grow up. He will not mind that there ever was a day when the toddling creatures set up a shout of delight at his entrance, and rushed at him, and scaled him, and searched his pockets, and pulled him about; nor that the day will never come when, growing into men and women, they will come to him for sympathy and guidance in their little trials and perplexities. Oh! woeful to think there are parents, held in general estimation, too, to whom their children would no more think of going for kindly sympathy, than they would think of going to Nova Zembla for warmth.—*Country Parson.*

**HABIT OF THE HIPPOPOTAMUS.**—There can be little doubt that the "Behemoth," of Scripture is identical with the animal we have named Hippopotamus. In the fortieth chapter of the book of Job, Behemoth is spoken of as an animal "that lieth down in the shade of the trees, in the covert of the reeds and fens:" "whose bones are as bars of iron." "He eateth grass, like an ox." "The shady trees cover him with their shadows; the willows of the brook compass him about." "Behold he drinketh up a river: he trusteth that he can draw up Jordan into his mouth." Although the researches of geologists have put it beyond doubt that, at a remote period of the world's history, the hippopotamus was common to Europe and Asia, it is now found only in Africa, and there not universally; with the exception of the Nile, none of the rivers that fall into the Mediterranean producing it. He is a shy brute, and retreats rapidly before civilization; indeed, it is only in the large and solitary rivers and lakes, running from the confines of the Cape Colony to about the twenty-third degree of north latitude, that the hippopotamus is found at home and at his ease. And no beast of the field can boast of a home so vastly grand and beautiful. Great silent lakes spread out on every side, with fairy islands dotting between—*islands* jutting green from the transparent water, and studded with the date, the black-stemmed mimosa, the wild wide spreading sycamore, the elegant mshoma, and other great straggling ragged fruit-bearers, the yellow, and scarlet, and pearly-white

fruit flickering and flashing in the sun, like colored lamps, and the wonderful fan palm, each leaf of which is as delicate and daintily shaped as a lady's fan, and which bears as fruit mahogany-coloured apples, that have for a core a round, hard, stony substance, like ivory. Through the rank underwood glide snakes of all the colours of the rainbow, and lizards, looking like animated masses of jewels; and above these dart and flutter birds, large and small, some with forked tails, and some with crowns, some vermilion, and some the colour of flame. The hippopotami at the Zoological Gardens, Regent's Park, are fine specimens. The larger of the two was shipped during its infancy, subsisting, during its voyage to England, on the milk of two cows and three goats. This, however, was soon found to be insufficient, so a few quarts of Indian meal were thrown in. By degrees he was "weaned," and vegetable diet supplied him instead of milk. At the present time his allowance is one hundredweight daily of hay, corn, bran, mangelwurzel, and white cabbage; and, during the ten years he has honoured this country by his presence, he has increased in weight more than a ton.—*Wild Sports of the World.*

**THE FLAX AND LINEN TRADE OF IRELAND.**—Belfast, the great emporium of the linen trade last year exported 65,000,000 yards of linen, and 13,200,000 lbs. of linen yard and thread. Next to importance to the flax industry is the trade in sewed muslins, employing about half a million persons in Ireland. Another manufacture carried on in Belfast is important in the consumption of agricultural produce—viz., starch-making from wheat. Ten firms use nearly 30,000 quarts of the finest red wheat every year. The wheaten starch made by the old fermentative process, is largely used by old bleachers, the goods retaining their stiffness longer than if dressed with rice and other starches. The whole of this business is at present paralyzed, as America was the best market for Irish linen goods, very limited quantities of which have been imported during the past nine months.

**Cows v. Horses.**—At a plowing match held on the estate of Right Hon. Earl Ducie, Crummel Park, we noticed a team of cows engaged in plowing at one end of the field; and as they appeared to excite a tolerable amount of attention, we thought it worth while to make a note or two on the spot. The animals were polled cows in full milk, and belonged to Mr. John Evans, of Woodford, Gloucestershire, who is, we believe, a small enterprising farmer. Two of the cows were rather old, the hindmost one, the owner assured us, had been worked regularly during the last seven years, and had had a calf every year, and one season was worked up to the day previous to calving. The middle cow was a three-year old, and this was her second season, the owner putting his cows to the plow at two years

old. Our readers must bear in mind that these cows were in full milk, being milked twice every day; on very hot days it was found necessary to milk them three times. Mr. Evans assured us that the cows gave more and richer milk when they were regularly worked, and that the goods were larger in amount, as well as better in quality; to use his own words when there was a less quality of goods made, his wife would tell him that he had not worked the cows so much, which was invariably the fact. Our readers will of course, imagine that the cows were, and ought to be well fed; hay, oil-cake bran and chaff, we were told, was the food given them during their working time. We give the opinion as to the policy of working dairy cows as above, leaving our readers to draw their own conclusion; we must say we thought it rather slow work, although the plowing was pretty well done, and there seemed no lack of strength or will on the part of the cows.

**AN EASY WAY TO DISSOLVE BONES.**—James S. Greenfield, practices dissolving bones by a method which seems worthy of notice from its simplicity and convenience. Casks having each but one head are provided; a layer of bones six or seven inches thick placed on the bottom; then strong, unleached wood ashes are spread over the bones to the thickness of two inches or more. The casks are filled in this way, taking care to have a pretty good thickness of ashes at the top to prevent the exhalation of ammonia. The process of thus packing the bones goes on through the season, as ashes accumulate in the house and they remain in the casks till spring, when the casks are emptied, and the bones are found to be generally well pulverized, or so soft that they can easily be broken as fine as desired. The mixed bones and ashes are excellent manure for most crops, and especially for fruit crops.—*Boston Cultivator.*

**PHYSICAL STRENGTH AND DEXTERITY.**—Physically, no man is made the most of. Look at an acrobat or a boxer: there is what your limb might have been made for strength and agility. That is the potential which is in human nature in these respects. I never witnessed a prize-fight, and assuredly I never will witness one; but I am told that when the champions appear in the ring, stripped for the combat (however bestial and blackguard-looking their countenances may be), the clearness and beauty of their skin testify, that by skilful physical discipline, a great deal more may be made of that human hide than is usually made of it. Then if you wish to know what may be made of the human muscles as regards rapid dexterity, look at the Wizard of the North or at an Indian Juggler. I am very far indeed from saying or thinking that this peculiar pre-eminence is worth the pains it must cost to acquire it. Not that I have a word to say against the man who maintains his children by bringing some one

faculty of the body to absolute perfection. I am ready even to admit that it is a very right and fit thing that one man in five or six millions should devote his life to showing the very utmost that can be made of the human frame, or the human muscular system as a whole. It is fit that a rare man here and there should cultivate some accomplishment to a perfection that looks magical just as it is fit that a man here and there should live in a house that cost a million of pounds to build, and round which a wide tract of country shows what might be made of trees and fields where unlimited wealth and exquisite taste have done their best to improve nature to the fairest forms of which it is capable. But even if it were possible, it would not be desirable that all human beings should live in dwellings like Hamilton Palace or Arundel Castle; and it would serve no good end at all—certainly no end worth the cost—to have all educated men as muscular as Tom Sayers, or swift of hand as Robert Houdin. Practical efficiency is wanted for the business of this life, not absolute perfection.—*Frazer's Magazine.*

**A GOOD SMOKEHOUSE.**—We lately observed a well-planned smokehouse on the premises of a good farmer, worthy of a brief description. It was about six feet square, the lower half built of brick, furnished with an iron-lined door, and serving as an ash-house, and place for the fire. The upper part about four feet high, besides the ascent of the roof, was made of wood. It was separated from the lower part by scantling joints, a space of two or three inches between them, through which smoke and air could freely pass, but sufficient to catch any ham that might accidentally fall, and thus save it from the fire. The upper part as well as the lower, was entered by a door from the outside; this upper door may be kept locked, except when admitting or withdrawing hams; but the lower may be left unlocked, for the hired men to build fires, without any danger of the contents above being stolen, as the thief cannot pass through the openings between the joists.—*Country Gentleman.*

**SEA-BIRDS.**—The question is often asked, where do sea-birds obtain fresh water to slake their thirst? but we have never seen it satisfactorily answered till a few days ago. An old skipper, with whom we were conversing on the subject, said that he had frequently seen these birds at sea, far from any land that could furnish them with water, hovering round and under a storm cloud, clattering like ducks on a hot day at a pond, and drinking in the drops of rain as they fell. They will smell a rain squall a hundred miles, or even further off, and send for it with almost incredible swiftness. How long sea-birds can exist without water is only a matter of conjecture; but probably their powers of enduring thirst are increased by habit, and possibly they can go without for many days, if not for several weeks.—*Wilson.*

**NOTES ON RAVEN STORIES.**—It is a curious fact that a bird of so grave and sedate a demeanour should so affect inns and taverns. Whether it is that, being burdened with an evil conscience, he seeks there to drown it—not by indulging in intoxicating liquor, but rather in the row and riot consequent on its absorption by morials; or whether, being of a cynical turn, he delights in the contemplation of folks going the same thing from the most opposite reasons—drinking, because they are jolly, and because they are miserable, because they can afford it, and because they are so wretchedly poor—is more than I can say. I only know that of the few remaining ravens in London, at least one half are attached to public-houses, and nearly always to such houses as adhere to the old custom of sign-posts and water-troughs. Some years ago there was attached to a tavern at Stoke Newington a raven, whose great antipathy was grey or white horses. Brown, black or roan horses might halt outside, and welcome; but so sure as one of the detested colour drew up and appeared at the water-trough, Peg was on the alert. She would perch on the edge of the trough and abuse the poor animal in the very choicest Billingsgate, or “gee, whoa!” in exact imitation of a carter, and start it off. I should have thought all this was done for pure fun and love of mischief, but for an incident related to me by the landlord, and which at once proved that the bird was actuated by sheer malice. It happened one day that Peg was particularly curious respecting a tobacco box belonging to a sailor who was drinking ale in the parlour. Presently the sailor took a “quid” from the box, and put it in his mouth. Peg watched the operation with great attention, and observing that the sailor relished the disgusting mouthful, as soon as his back was turned she darted at the box and swallowed its contents at a gulp. The consequence was that for the remainder of that day and the next she was very ill indeed. A few days after an unlucky white horse, attached to a hay-cart, arrived at the house in question, and was drawn up to the trough to drink, and the raven instantly began her persecution. The white horse, however, had met Peg several times before, and had learned to treat her impudence with indifference. Finding abuse and assault of no avail, Peg turned into the house, and, finding some men smoking in the taproom, she caught up a paper of tobacco from the table, flew to the edge of the trough with it, and deliberately dropped it into the horse’s nose-bag.—*Home Pets, (Oct.)*

**THE NEW ARTESIAN WELL NEAR PARIS.**—The sinking of the artesian well at Paris cost £40,000. The result is, however, beyond all previous calculation. Instead of the 12,000, no less than 75,000 cubic feet spring up every twenty-four hours—the well at Grenelle giving only 3,000 at the utmost, now reduced to 2,200 cubic feet.

The Passy bore is 60 inches in diameter, and quite a river of pure water flows from it, equal in quantity to one thirty-fifth of the average flow of the Seine! With a few such wells all Paris could be supplied, and at a trifling cost compared with that of the gigantic schemes for bringing water from Champagne and other quarters. The temperature is high—80 degrees—and in this state it can be made very useful for many purposes, though for drinking it must be cooled.

**WORKS OF HUMAN LABOUR.**—Nineveh was 15 miles long, 8 wide, and forty miles round, with a wall 100 feet high, and thick enough for three chariots abreast. Babylon was 50 miles within the walls, which were 75 feet thick and 100 high, with a 100 brazen gates. The temple of Dagon, Ephesus, was 420 feet to the support of the roof; it was a hundred years in building. The largest of the pyramids is 481 feet high, and 653 on the sides; its base covers 11 acres. The stones are about 60 feet in length, and the layers are 208. It employed 330,000 men in building. The labyrinth in Egypt contains 300 chambers and 12 halls. Thebes, in Egypt, presents ruins 27 miles round, and 100 gates. Carthage was 29 round. Athens was 25 miles round, and contained 359,000 citizens and 400,000 slaves. The temple at Delphos was so rich in donations, that it was plundered of \$50,000,000, and Nero carried away from it 200 statues. The walls of Rome were 13 miles round.

**SLEEP VS. INSANITY.**—In an article on sleep in a late number of the *Edinburgh*, Dr. Cornhill, of Philadelphia, says:—The most frequent and immediate cause of insanity, and one of the most important to guard against, is the want of sleep. Indeed so rarely do we see a recent case of insanity that is not preceded by want of sleep, that it is regarded as almost a sure precursor of mental derangement. Notwithstanding strong hereditary predisposition, ill health, loss of kindred or property, insanity rarely results, unless the exciting causes are such as to produce a loss of sleep. A mother loses her only child; a merchant his fortune; the politician, the scholar, the enthusiast may have their minds powerfully excited and disturbed; yet, if they sleep well, they will not become insane. No advice is so good, therefore, to those who have recovered from an attack, or to those who are in delicate health, as that of securing, by all means, sound regular, and refreshing sleep. "There is no fact," says Dr. Spenser, "more clearly established in the physiology of man than this, that the brain expands its energies and itself during the hours of wakefulness, and that these are recuperated during sleep; if the recuperation does not equal the expenditure, the brain withers—this is insanity. Thus it is that in early English history, persons who were condemned to death by being prevented from sleeping, always died raving maniacs; thus it is, also, that those who starve to death become insane; the brain is not nourished, and they cannot sleep."

**USEFUL MEDICAL HINTS.**—We find the following remarks (by the editor) in the *Cincinnati*, a scientific and agricultural journal published at Cincinnati, Ohio:—If a person swallows any poison whatever, or has fallen into any convulsions from having overloaded the stomach, an instant and easy remedy is a teaspoonful of common salt and as much ground mustard, stirred rapidly in a teacup of water, warm or cold, and swallowed instantly. It is scarcely down before it begins to come up, bringing with it the contents of the stomach; and lest there be any amount of poison, however small, let the white of an egg or teacup full of strong coffee be swallowed as soon as the stomach is quiet; because these nullify many virulent poisons. In case of scalding or burning the body, immersing the part in cold water gives entire relief, as instantaneously as the lightning. Meanwhile, get some common dry flour, and apply it an inch or two thick on the injured part the moment it emerges from the water, and keep sprinkling on the flour through anything like a pepper-box cover, so as to put it on evenly. Do nothing else; drink nothing but water; eat nothing until improvement commences, except some dry bread softened in very weak tea of some kind. Cures of frightful burnings have been performed in this way, as wonderful as they are painless. We once saved the life of an infant which had been inadvertently drugged with laudanum, which was fast sinking into the sleep which has no waking, by giving it strong coffee, cleared with the white of an egg—a teaspoonful every five minutes—until it ceased to be drowsy.

**HOW TO TREAT THE BITE OF A DOG.**—Dr. Stephen Ware, of Boston, in his testimony of a recent case which grew out of the injuries from the bite of a dog, furnished the following valuable advice:—In the case of a bite by a dog, where the teeth of the animal penetrated the flesh, whether the dog was known to be mad or not, he should use the same precautions. He would wash the wound with warm water, extract all the virus possible by sucking the wound with his lips, and then canterize it deeply with the caustic most readily obtained, but should use potash if it could be procured at once. The time in which the effects of the bite of a mad dog would be seen, varied from two to three days to as many years, but if no effects were felt after two or three months, as a general thing the patient might consider himself safe. Bites made through clothing are seldom productive of much harm, as even if the dog is mad the clothing absorbs the virus before the teeth reach the flesh. Most of all the fatal cases are where the person was bitten on some naked part. Concerning the possibility of a cure in a real case of hydrophobia nothing was said.

**WATER TO DRINK FOR SOLDIERS.**—Mr. Henry Marshall, who was for a long period Deputy

Inspector of Hospitals, in the British Army, says:—"By the daily custom of imbibing spirituous potations a new want is created, intemperance is established as a habit, and frequent intoxication is the consequence. The wretched drunkard must now have a large supply of liquor in the morning to recover from the effects of the quantity drank on the previous night. He perhaps has neither money nor credit, and his clothes are then sold at a small portion of their value. Some do not stop here; for, after having sold all their clothes, they will rob their comrades and with the proceeds of their dishonesty provide the means of intoxication. Confinement follows upon confinement, court-martial upon court-martial, and punishment upon punishment, until the worn out wretch dies in hospital of the 'horrors,' fever or dysentery; or if he should for a time resist the fatal attacks of disease, his constitution becomes broken down by the combined influence of the poison of spirits, an exhausting climate and repeated attacks of illness, so that, in a few years, he is found unfit for further service in India."

The personal experience of Mr. Marshall was decidedly in favor of the superior sanitary effects of water drinking, in hot climates. He says:—"I have myself marched on foot with troops on actual service, in a tropical climate, where the mean temperature is considerably higher than that of Jamaica, without any other beverage than water, and occasionally a cup of coffee. So far from being calculated to assist the human body in enduring fatigue, I have always found that the strongest liquors were the most enervating; and this in whatever quantity they were consumed, for the daily use of spirits is an evil which retains its pernicious character through all its gradations. Indulged in at all, it can produce nothing better than a diluted or mitigated kind of mischief." Dr. Robert Jackson, who was at one time at the head of the medical staff in the West Indies, expresses his opinion that an English soldier, aided by temperance, may be rendered capable of going through the severest military duty in the hottest islands in the West Indies.

Whiskey was unknown among the iron soldiers of Rome, who were the conquerors of the world. Water was their common drink, sometimes modified by weak sour wine, almost resembling vinegar.

**RULES FOR READING.**—Read the best books which wise and sensible persons advise, and study them with reflection and examination. Read with a firm determination to make use of all you read. Do not, by reading, neglect a more immediate or more important duty. Do not read with a view to make a display of your reading. Do not read too much at a time. Reflect upon what you read, and let it be moderately enjoyed and well digested.

**THE BASHFUL MAN.**—Washington Irving, at a party in England, once told the following story of a bashful friend of his, who, being asked to a dinner-party, sat down to the table next to the hostess in a great state of excitement, owing to his reclusive life. A few glasses of wine, mounting to his brain, completed his confusion, and dissipated the small remains of his presence of mind. Casting his eyes down, he saw on his lap some white linen. "My heavens!" thought he, "that's my shirt protruding at my waist-band." He immediately commenced to tuck in the offending portion of his dress; but the more he tucked in, the more there seemed to remain; at last he made a desperate effort, when a sudden crash aroused him, and screams from the company brought him to his senses. He had been all the time stuffing the table-cloth into his breeches, and the last attempt had swept everything clean off the table. Thus our bashful friend annexed a table cloth, thinking it was the tail of his own shirt.

### Editorial Notices, &c.

THE JOURNAL OF THE BOARD OF ARTS AND MANUFACTURES OF UPPER CANADA: TORONTO.

The first number of Vol. 2 has just come to hand of this useful periodical, and its contents contain much to interest not only the mechanic and manufacturer, but also the general reader. In a young country like Canada, to rouse a spirit of energy and emulation in relation to arts and manufactures, must always be a slow and sometimes difficult work; and this is felt to be more particularly the case at the commencement and during the early stages of such undertakings. We are glad, therefore to find that the exertions of our Board of Arts and Manufactures have already been attended by such an amount of success as to encourage them to bring out their Journal for the current year in an enlarged and improved form, without increasing the price. The present number indicates much care and skill in preparing and editing the various subjects of which it treats, some of which are well illustrated by appropriate wood cuts. Its "getting up," as well as its scientific and literary matter are alike creditable to all concerned in its production. We will only add, that to single subscribers the yearly subscription is \$1; to clubs of ten or

more 75 cents; but members of Mechanics' Institutions, and also those of *Agricultural Societies*, can procure the work for the very small sum of 50 cents a year! Communications should be addressed to W. Edwards, Esq., Secretary of the Board of Arts and Manufactures, Toronto.

THE GARDENERS' MONTHLY: Edited by Thos. Meehan; Philadelphia, January 7, 1862.

This excellent gardening periodical has entered on its fourth year, with a constant tendency to improvement, so that it may now be considered as being permanently established. All subjects connected with Horticulture, in its various departments, the management of orchards, &c., are treated in its pages with a fullness and practical skill that must be highly acceptable to all who are in any way interested in these important and pleasing pursuits. We shall be happy to know that the *Gardeners' Monthly* is being increasingly circulated in every county and township in the Province. In this manner the taste and domestic comforts of the people would most surely be raised and increased. A good vegetable garden and orchard are among the indispensables to the enjoyments of a country life; and the cultivation of a few flowers, and the proper grouping of a few shrubs and trees around a country home, very much tend to increase its beauty and attractiveness. Mr. Fleming, Seedsman and Florist, of this city, will supply subscribers with this interesting and useful work for one dollar a year, a sum extraordinarily low, when its execution and the character of its papers are taken into consideration.

THE RURAL ANNUAL AND HORTICULTURAL DIRECTORY, for the year 1862: Rochester, N. Y., Joseph Harris.

This is the seventh annual publication of this very useful and popular Annual, the high character of which is fully sustained by the present volume. It is, as several of our readers are aware, published by Mr. Joseph Harris, at the office of the *Genesee Farmer*, at Rochester, in the state of New York, from whence it can be obtained by mail, by remitting the price, only 25 cents! This small sum will appear extraordinary when it is considered that the work is very neatly printed, and illustrated by numerous wood cuts. Publications of this nature cannot fail to ensure a highly beneficial influence on the

practice of agriculture, and the minds of all that are in any way engaged in country pursuits.

Among the contents of this volume we notice articles on the culture of Apples, Pears, Peaches, Plums, Grapes, etc., with a list of good varieties; also of Strawberries, Raspberries, Currants, etc.; on Annuals and their Culture; on the Manufacture of Domestic Wines; on the Cultivation of Wheat, Barley, Oats, Rye, and Indian Corn; on Cutting Potatoes for Planting; on Harrowing Potatoes; Chinese Hogs; English Mutton Sheep; Making Hay; Covering Grass Land with Straw; Culture of Figs; on Poultry; on the Culture of the Peach in the Middle States; Fruit and Malaria; Protecting Plants from Frost; Summer Pruning Apples; Rules for Arranging Ornamental Grounds; Fire-proof Wash for Roofs, etc.; on Cider-Making; Seeding with Clover among Corn; to Kill Canada Thistles; Amount of Roots from Clover and Grasses; to Destroy Insects, the Poultry Mildew; Trimming Osage Orange Hedges; Cultivation of the White Bean; Moss on Roofs; Whitewash; a Novel Ice-House; Application of Manure; Toads and Bees; on the Cultivation of Dwarf and Standard Pears; Mulching the Currant; Mildew on the Grape; Spireas and their Culture; Cold Graperies; When to Gather Grapes; Low-Headed Trees; the Delaware Grape; Strawberries; Aphides on trees; Covering Grape Vines in Winter; Aerating the soil; Warts on Cattle; Cut Worm and Corn Grub Killer; Treatment of Milk Cows, etc., etc.

TO AGENTS AND SUBSCRIBERS.—We beg to remind officers of Agricultural Societies and other gentlemen who are in the habit of obtaining subscriptions for this Journal, as well as our readers generally, that it is our invariable practice to stop all papers as soon as the term for which the subscription has been paid has expired. The paper is not again forwarded till the order has been renewed and the amount remitted. Agents will therefore please give this explanation to any subscribers of last year who may not understand the reason of their not receiving our journal since the commencement of the new year. We have already a large proportion of last year's subscribers on our books again for this year, and we shall be happy to receive the whole, with any number in addition, as soon as they please to forward their orders.

## BOARD OF AGRICULTURE.

THE Office of the Board of Agriculture has been removed to 188 King Street West, a few doors from the late location adjoining the Government House. Agriculturists and any others who may be so disposed are invited to call and examine the Library, &c., when convenient.

HUGH C. THOMSON,  
Toronto, 1861. Secretary.

International Exhibition, London,  
1862.

THE Commissioners for Canada at the INTERNATIONAL EXHIBITION of 1862, give notice to all parties desirous of exhibiting Canadian products, whether application has been already made for the exhibition of the same or not, that such articles may be sent in for examination and approval to the following places, at any time between the TENTH DAY of FEBRUARY next, and the undermentioned dates, viz:—

IN CANADA WEST.—London, 18th February; Hamilton, 20th February; Toronto, 22nd February; Kingston, 25th February, and Ottawa, 28th February.

IN CANADA EAST.—Quebec, 14th February; Three Rivers, 18th February; St. Hyacinthe, 22nd February; Sherbrooke, 25th February next; and Montreal, 3rd and 4th March next.

Articles will be received and stored at the Depots of the Grand Trunk Railway Company at London, Toronto, Kingston, Quebec, Point Levi, Sherbrooke and St. Hyacinthe.

The Commissioners will begin their examinations at 10 o'clock, A. M., of each day named.

Intending exhibitors must deliver the articles for exhibition at the above named places, free of charge. Should they not be approved, the Grand Trunk Railway will return them free of charge, to any depot on their line from which they have been sent.

Parties sending in Grain or Woods are requested to transmit a certificate, stating the species and varieties, and where grown. Woods should be sent of the usual dimensions for commerce, and Her Majesty's Commissioners have expressed a desire that they be shown in planks 4 inches thick, showing the sap on both sides, or in 4 inch scantling, and accompanied, wherever practicable, by twigs with leaves or flowers.

Parties desirous of further information, may apply, concerning Minerals and Specimens of Economic Geology, to Sir W. E. Logan, Montreal; concerning products of the Forests and Waters, to Dr. Tache, Quebec, or Dr. Hurlburt, Hamilton; concerning Agricultural produce, to Hon. L. V. Sicotte, St. Hyacinthe, and Col. Thomson, Toronto; concerning articles of Canadian Manufacture, to Dr. Beatty, Cobourg, or to the Secretary, Montreal, to whom also, communications on all other business of the Commission are to be addressed.

R. CHAMBERLIN, Com'r, Secretary.  
Montreal, December 12, 1861.

## Notice of Co-Partnership.

THE Undersigned have entered into Partnership as Seedsmen and dealers in all kinds of Agricultural and Horticultural Implements, under the firm of James Fleming & Co.

JAMES FLEMING,  
GEORGE W. BUCKLAND.

## NOTICE.

JAMES FLEMING & CO., Seedsmen to the Agricultural Association of Upper Canada, will carry on the above business, wholesale and Retail, at 126 Yonge st., 4 doors North of Adelaide-street, until next July, when they will remove to the new Agricultural Hall, at the corner of Queen and Yonge streets.

JAMES FLEMING will continue the business of Retail Seedsmen and Florist at his old stand, 350 Yonge-street.

Toronto, January 1st, 1861.

## FOR SALE.

AT

WOODHILL, WATERDOWN P. O.

MR. FERGUSSON expects to have several *pure Durham bull calves* to dispose of next Spring, 1862, not intending to raise any this season. These calves will be all of the *well known DUCHESS tribe*, and will be put on the G. W. R. R. at six weeks old for eighty dollars each.

N. B.—First come, first served.

Waterdown, Nov. 14, 1861.

4-t.

## THOROUGH BRED STOCK FOR SALE.

THE SUBSCRIBER has for Sale Durham and Galloway Cattle, male and female.

Leicester, Cotswold, and Lincolnshire Sheep, male and female.

January 1, 1862.

tf.

JOHN SNELL,  
Edmonton, P. O., C. W.

## VETERINARY SURGEON.

ANDREW SMITH, Licentiate of the Edinburgh Veterinary College, and by appointment, Veterinary Surgeon to the Board of Agriculture of Upper Canada, respectfully announces that he has obtained those stables and part of the premises heretofore occupied by John Worthington, Esq., situated corner of Bay and Temperance streets, and which are being fitted up as a *Veterinary Infirmary*.

Medicines for Horses and Cattle always on hand. Horses examined as to soundness, &c.

Veterinary Establishment, Corner of Bay and Temperance Sts.

Toronto, January 22nd, 1862.

**FOR SALE.**

**A FEW PURE-BRED SOUTH-DOWN RAMS**  
and Ewe Lambs, from

**IMPORTED STOCK,**

Selected from the Best Flock-dealers in Dorset,  
Wilts, and Hants.

The Subscriber will Warrant these Lambs to  
produce as much Wool and Mutton, and of  
equal Quality, as those of Jonas Webb, or any  
other Flock of the same kind and number in  
England.

JOHN SPENCER,  
Brooklin, Post Office,

Oct. 12th, 1861. Ontario County C. W.

**AYRSHIRE BULL FOR SALE.**

**MR.** Denison, of Dover Court, offers for Sale  
a thorough bred Ayrshire Bull, bred by  
the celebrated Ayrshire breeder, John Dodd,  
Esq., of Montreal. The bull is 3 years old, and  
can be delivered at or after the Show at Lon-  
don, in September.

Toronto, Aug., 1861.

**\* THE****JOURNAL OF THE BOARD OF ARTS  
AND MANUFACTURES,****FOR UPPER CANADA,**

Is Published on the first of every Month.

**A**T \$1 per annum for single copies, or to clubs  
of ten or more at 75 cents. per copy; to  
members of Mechanics' Institutes, and of Liter-

No. 3.

### The Early History of Agricultural Societies in Canada.

EDITORS OF THE AGRICULTURIST,—GENTLEMEN,—For many years I have wished to gather information respecting the early history of Agricultural Societies in this Province, from the gentlemen who first established them, with the view of preparing a little history therefrom some day at my leisure.

The first parliamentary law passed for the organization of Agricultural Societies was in the year 1830, and, immediately afterwards these valuable societies began to spring up and flourish in many of the older districts of the province. Before the passage of the law for their establishment some districts were partially organized, the Home District being among the number, and, if I mistake not, there was also a Society at Kingston, and another at Cobourg, started previous to the Agricultural Bill. Of these, we have no report as far as I can learn, and never shall have, unless provided for us by the early promoters of them, and these, I fear, are not very numerous at the present day. I can, however, name a few gentlemen whose connection with these societies, and doubtless the proposers of them, are still living, and could furnish valuable information. I refer to Colonel E. W. Thomson and W. B. Jarvis, Esq., of the old Home District; Col. J. B. Marks, of Frontenac, Lennox and Addington, and the Hon. Henry Ruttan, of Northumberland, Durham, &c. &c. If these gentlemen would take the trouble to try back in their storehouses of memory, and furnish such a history as they only can furnish of the societies named above, or any others, giving the objects for which they established them, and some of the names

of their colleagues, and earliest importers of stock, &c., with any documents they may have, such as By-laws, Show Bills, or Prize lists, they would confer a favour. Of course all the societies organized under the Statute can be traced by the reports they furnished to Parliament, in accordance with the law.

With this little history, brought up to the year 1847, when the law was passed to incorporate the Agricultural Association, which was commenced the year previous, we should have all that may ever be expected, and who knows how much it may be prized by our descendants, and especially those descended from the fathers of Agricultural Societies in Upper Canada.

Yours, &c.,

RICHARD L. DENISON,

Dover Court, Feb., 1862.

### Elodea Canadensis.

TO THE EDITOR OF THE CANADIAN AGRICULTURIST,—SIR—I am not prepared to answer the question you proposed (page 584), "Is the *Elodea Canadensis* known in Canada?" But if it is not, *unde derivatum*? whence its name? Gray mentions but two varieties, *Virginica* and *petiolata*—the latter from New Jersey, southward and westward. He describes, however, a member of another family, the *frog's bit*, (the *Elodea*, he says, is a *St. John's wort*) the *Anacharis water-weed*, which may perhaps be the plant in question. At all events the name is more suitable to so mischievous a weed as the one described in the article that has elicited these remarks, a weed altogether destitute of charms. It would seem that neither of these plants is intended to flourish in rivers possessing a rapid current. They are *marsh* or *pond* plants, and rejoice in such waters as are slug-

gish, if not stagnant, and unobstructed by boats, or drift-wood, or other extraneous matters calculated to injure their very fragile stalks.

Paxon gives us only two species of *Elodea*, which, by-the-bye, he terms "interesting aquatics," *Guianensis*, from Guiana, and *pulchella*, from the East Indies. He makes no allusion to a Canadian species. He assigns the *Elodea* to the *Frog's-bit* family.

Gray and Paxton are both recognized authorities; so after all I fear I have made "confusion worse confounded."

I am, Sir, your obedient Servant,

V. C.

Peterboro', C.W.. Nov. 21, 1861.

[The above communication should have appeared several weeks ago, but got accidentally mislaid, and was not discovered again till a few days back,—Ed.]

### International Exhibition, 1862.

The subjoined official notice has been issued by the commissioners:—Her Majesty's Commissioners have adapted the following regulations with respect to the admission of visitors to the exhibition:

1. The exhibition will open, as previously announced, on Thursday, the 1st of May, and will be open daily (Sundays excepted) during such hours as the commissioners shall, from time to time, appoint.

2. The Royal Horticultural Society having arranged a new entrance to their gardens from Kensington-road, the commissioners have agreed with the council of the Society to establish an entrance to the Exhibition from the Gardens, and to issue a joint ticket giving the owner the privilege of admission both to the gardens and to the Exhibition on all occasions when they are open to visitors, including the flower shows and *fetes* held in the Gardens, up to the 18th of October, 1862.

3. There will, therefore, be four principal entrances for visitors:—(1.) From the Horticultural Gardens for the owners of the joint tickets, fellows of the society, and other visitors to the garden. (2.) In Cromwell-road. (3.) In Prince Albert's-road. (4.) In Exhibition-road.

4. The regulations necessary for preventing obstructions and danger at the several entrances will be issued prior to the opening.

5. Admittance to the Exhibition will be given only to the owners of season tickets, and to visitors paying at the doors.

6. There will be two classes of season tickets; the 1st, price £3 3s, will entitle the owner to admission to the opening and all other ceremonials, as well as at all times when the building is open to the public; the 2nd, price £5 5s,

will confer the same privileges of admission to the exhibition, and will further entitle the owner to admission to the Gardens of the Royal Horticultural Society at South Kensington and Chiswick (including the flower show and *fetes* at these gardens) during the continuance of the Exhibition.

7. On the 1st of May, on the occasion of the opening ceremonial, the admissions will be restricted to owners of season tickets.

8. On the 2nd and 3rd of May the price of admission will be £1 for each person; and the commissioners reserve to themselves the power of appointing three other days, when the same charge will be made.

9. From the 5th to the 17th of May, 5s.

10. From the 19th to the 31st of May, 2s 6d, except on one day in each week, when the charge will be 5s.

11. After the 31st of May the price of admission on four days each week will be 1s.

12. Season tickets are now for sale, between the hours of 10 and 5 daily, at the offices of her Majesty's Commissioners, No. 454 West Strand, London, W. C.

13. Application through the post (stating Christian name and surname) must be addressed to the secretary, and must be accompanied by Post-office orders, payable to J. J. Mayo, Esq., at the Post-office, Charing-cross.

14. No cheques or country notes will be received.

15. Cases for preserving the season tickets may be obtained at the office for 1s each.

### On Feeding Stock.

*Continued from Page 44.)*

It is difficult, among these conflicting statements, to decide as to what is to be considered the real effect of salt. But, fortunately, we possess a very remarkable series of experiments by Voit, whose object was to elucidate the general question of the influence of salt in the nutrition of animals, on which they throw a good deal of light. His experiments were made on the dog, which, from its small size and docility, is well fitted for the purpose. The dog used, for the experiments required, 1,500 grammes of flesh to maintain its weight. As soon as it was supplied with salt, it began to drink a larger quantity of water, and to secrete more urine, and the proportion was:—

|                      |              |
|----------------------|--------------|
| No salt, .....       | 935 grammes. |
| 5 Grammes daily..... | 948 "        |
| 10 " .....           | 1042 "       |
| 20 " .....           | 1284 "       |

It may be supposed that this increase is due to the larger quantity of water drunk; but this is not the case, for when the animal was not allowed to drink, it was nevertheless found that

the urine increased in just the same proportion, the quantities being:—

|                      |              |
|----------------------|--------------|
| No salt, .....       | 828 grammes. |
| 5 Grammes daily..... | 898 “        |
| 10 “ .....           | 987 “        |
| 20 “ .....           | 1124 “       |

The urine was not only increased, but it contained more of the peculiar principle of the urine called *urea*, the numbers being, in the course of the whole experiment:—

|                 |       |
|-----------------|-------|
| No salt .....   | 107.4 |
| 5 Grammes ..... | 109.5 |
| 10 “ .....      | 110.9 |
| 20 “ .....      | 112.8 |

The importance of this observation will be understood when it is borne in mind that the *urea* affords a measure of the quantity of the tissues disintegrated and excreted, and that the presence of a larger quantity than usual in the urine is a proof that an increase of food is necessary to maintain the true weight of the animal. Such was, in fact, found to be the case, and the dog fell off in weight when it got the salt with its food. These experiments, therefore, tend to confirm those of Boussingault, and show that salt does not cause the animal to make a better use of its food; on the contrary, the effect is in the opposite direction, so that in economical feeding more salt should not be used than is just sufficient for the requirements of the animal. On the other hand, it must not fall short of this quantity; and to secure a proportion, the nature of the food should be taken into account, so that if much straw, and more especially straw grown at a distance from the sea, is used, a small addition should be made to the food, but it should always be small, and it should not be given *ad libitum*, but in the smallest quantity consistent with fulfilling its object. On exactly the same principle as the addition of salt has been recommended, it has been proposed to employ phosphate of lime. That substance, as we all know, is an indispensable constituent of the animal body, and, besides, forming the larger part of the bones, is met with in almost all the other organs. It is a substance, also, in which the food is sometimes deficient, and it has been maintained that in most cases an additional quantity should be beneficial. There is no doubt that when it and other mineral constituents of the food are in too small quantity, the health suffers, and a remarkable instance of this is found among the experiments of Messrs. Lawes and Gilbert. They fed these swine for eight weeks on maize, a substance containing a very small quantity of mineral matters, and more especially of phosphates, and they began to suffer from swelling of the glands and other bad symptoms. They were then supplied with a mixture of 5lbs. wood ashes, 1lb salt, and  $\frac{1}{2}$  lb. of superphosphate, every fourteen days, and this nauseous mixture they greedily devoured and soon regained their health, while others

which did not get it died. Several series of experiments have been made in which phosphate of lime, in the form of extremely fine powder, has been added to the food of animals, and the results, as in the case of salt, have been exceedingly conflicting. Lehmann made one series, in which he obtained a favourable result. He gave exactly the same food to three young pigs, two of which got daily half an ounce of finely ground bone earth, and these, at the end of 259 days, weighed respectively 23, and 11 lbs. more than the third, which got none. In another experiment, made in Silesia, and also on swine, no perceptible difference existed between the two lots. In a third series, made by Von Barratta on lambs, bone meal was employed to the extent of half an ounce daily, and here the results were most unfavourable, for the lambs which got it weighed, at the end of 40 days, 31 lbs. less than those which got none. In this case, however, the effect may be due to the animal matter of the bone meal, which may not be suited to the herbivorous animal. A more minute and careful series of experiments on the influence of phosphate of lime on lambs has recently been made by Von Gohren, which lead to the conclusion that it does not affect their growth in any way, the weight of those receiving 120 grains daily being sensibly the same as that of those which had none. By comparative analysis, however, of the food and excretions, he has ascertained that a portion of the phosphate of lime was actually absorbed and employed within the system. Where no phosphate of lime was used, the excretions contained 3.5 grains of phosphoric acid less than the food, so that this was the quantity daily stored up in the system. But when bone earth was added to the food, 28.10 grains were retained daily. It thus appears that the phosphate of lime, like salt, has no effect in increasing the live weight of the animals to which it is given, or in causing them to make a better use of their food; but it is quite possible that where there is a deficiency in the phosphoric acid it may exert an important influence on the health of the animal during the early period of life, when the bone is chiefly formed, and hence its use may occasionally be advantageous.

The general conclusion to be drawn from all the experiments and observations now detailed is that whatever benefits may accrue to the health of the animal by the use of condiments, of which common salt may be taken as the type they are without effect on the quantity of nutritious matters assimilated; and salt, when used in considerable quantity, actually causes the expenditure of an extra quantity of food to produce the same increase in live weight. These facts are not unimportant in relation to a class of substances now commonly called “condimental foods,” which are very actively pressed upon the attention of the farmer, and are alleged to produce so great an economy of the ordinary

food as to justify the high price at which they are sold. It is worthy of notice that the grounds upon which these substances are offered have been somewhat changed. They were originally called "concentrated foods," a term clearly borrowed from that used in describing manures, and intended to lead to the belief that the nutritive elements of the plant food are found in a guano or superphosphate. This view of the matter is exceedingly specious and attractive, but a very little consideration suffices to show that it is entirely fallacious. A manure can be concentrated, because it contains many substances of little or no use to the plants. Thus it would be possible, though not practically economical, to take farm-yard manure containing about 75 per cent. of water, and by simply drying it, to concentrate four tons into one. It would be even possible to go still further, and to extract from it the ammonia, phosphoric acid, and other substances required by the plant, and so to reduce it to a still smaller bulk; but no such concentration is practicable with the food of animals. The two great kingdoms of organised beings are, no doubt, made up of exactly the same chemical elements, but the plant is able to take its food in the form of simple compounds, such as the ammonia, carbonic acid, &c., and from them to build up the most complex constituents of its frame. But animals possess no such power; their food must be supplied to them in the form of those complex and bulky compounds which the plant alone can produce, and which the animal only modifies to a slight extent in the process of assimilation. Hence it follows that it is only theoretically possible to concentrate the food of animals to a very limited extent, because the quantity of innutritious matters each of them contains is small, and it is *practically* impossible to do it at all, because there are no processes known by which the innutritious matters can be removed in such a manner as to leave the nutritive substances in a state in which they can be used as food. In the grains of the cereals the only absolutely innutritious substances are water and a small quantity of woody fibre, of which the latter cannot be extracted without entirely destroying the grain; and, though the former may be expelled by heat, it is rapidly reabsorbed from the air.

The food of an animal cannot therefore be concentrated, and the introduction of the word "condimental" instead of the "concentrated" food by the makers of some of these articles must be taken as a tacit admission that this view of the case cannot be defended. The fact is, that analysis at once shows that in these substances there has really been no concentration. A minute examination of a number of them recently made in the laboratory, which will appear in the forthcoming number of the "Transactions," has shown that there has been no attempt to concentrate in the sense in which that word is usually understood, for they all contain just as

much water and woody fibre as other vegetable substances, and are, in fact, mixtures of the most ordinary materials, consisting of Indian corn, rice, bean meal, ground carob beans, and other similar substances, along with small quantities of aromatic seeds, and in some instances a bitter substance, apparently genian. It is absurd to suppose that the contents of a small tin measure holding half a pint of these substances can be used to replace one half of the ordinary food of an ox or a horse, and their inventors, seeing that as these facts became known to the farmer their position would become untenable, have taken refuge behind the aromatics and bitters they contain, and have asserted that their effect is condimental, and that they act by promoting digestion and causing the animal to extract and assimilate a larger quantity of the nutritive matters of its ordinary food. They have obviously gone upon the commonly received opinion, which attributes to salt and similar substances this effect—a view which the facts I have already detailed by no means countenance. There is, in fact, not the slightest reason to suppose that the substances contained in these have any such effect. They consist, in addition to the grains already mentioned, chiefly of fecungrec and caraway seeds, and one of those I have examined contained so large a quantity of turmeric that it might almost be described as a curry powder. Nothing definite is known regarding the action of these substances on the system, there being no experiments such as those by which the effects of salt have been determined; and there is no evidence to support the view that they are capable of producing a more complete assimilation of the food, but every reason to believe the reverse. In fact, when a dispassionate view of the matter is taken, I think that it can scarcely be doubted that, if small quantities of caraway or other aromatic seeds were given to animals, and their weights carefully determined, it would be found that they are quite without effect. It must be noticed that there have been no attempts on the part of the "discoverers" to produce such accurate experiments in support of their views, although there have been plenty of general testimonials, such as every quack medicine can produce by the score, and abundance of vague declamation regarding their wonderful effects. The plain fact is, that science does not give the slightest support to the idea that these substances have any effect whatever; and in saying so, I am only stating an opinion in which all chemists will concur, and which has, indeed, been often stated before. Its accuracy has just as often been denied by the makers of these articles, but it has never been disproved, nor will that be possible until they can produce the precise results of trustworthy experimenters in support of their substances. But even admitting the accuracy of all the statements put forth by the makers of their food, there is another question which merits attention, and that is the

price at which they sold. I have already mentioned that they are composed chiefly of some of the more familiar foods mixed with a small quantity of aromatics. The exact proportion in which these latter substances exists in them cannot be accurately determined, but it is not large, and does not exceed 10 per cent. Indian corn, carob beans, &c., cost about £8 or £9 per ton, and fœcungiee and caraway seeds £20 to £25. A mixture of nine tons of the former, and one of the latter, should therefore be sold at £10 or £11 per ton, in place of £20 or £30, the price actually charged; so that if these goods do produce the alleged effect, the farmer is made to pay for them three times their intrinsic value. This fact is of itself a sufficient comment on what has been already stated, and the truth is that the "discoveries" of which the makers of these foods boast are confined to the art of extracting money from the pockets of the farmer.

The general conclusions to be drawn from what has now been said may be summed up in a very few words:—1st, Common salt, the most important condiment, has no effect in promoting the assimilation of the food, and, when used in *large* quantity, has rather a tendency to produce a waste of nutritive matters; 2nd, Both it and phosphate of lime, and probably other mineral substances, may exercise a beneficial effect on its health when the quantity existing in the food is less than the animal requires; 3rd, There is not the slightest reason to suppose that the so-called condimental foods produce any effect on the animal, as they consist only of ordinary grains mixed with small quantities of aromatic and bitter substances, which, so far as our present knowledge goes, do not in any way affect the nutrition of animals.

### Flax Culture.

As the question of Flax cultivation is now on the tapis, and as I am thoroughly convinced of its importance, both as regards the interests of the farmers as individuals and the Province as a nation, I beg to send you the following remarks.

I see by the Annual Report of the Directors of the North Oxford Agricultural Society, in last week's *Times*, that the Hon. G. Alexander and Mr. Penman have very liberally offered to give ten dollars each as a prize or prizes for the best samples of flax grown in the North Riding next year. With all due deference to those gentlemen, I would beg to suggest that the offering of prizes is not alone sufficient to insure the growth of such a quantity as would pay the interest on capital expended in the erection of a scutching mill. The majority of the farmers know little or nothing about the cultivation of the plant, and consequently will be unwilling to expend money and labour upon its growth, unless previously well assured of its proving remunerative. The surest way, in my opinion,

would be to form a Company with such a capital as would enable them, after erecting a house with machinery, to purchase flax seed, and by advertisements inform the farmers that they could have seed for any amount of land they would guarantee to sow; the Company taking their notes for the amount, redeemable by so much flax (of course at market price) at the end of the year. Such a system would enable the farmers to try the experiment without any outlay in hard cash, and that, with not a few, is a desideratum.

And a still greater inducement would be for such a Company to start Schenk's process of preparation, viz: to steam the flax for the purpose of separating the wood fibres, instead of steeping it in water; and to purchase the flax from the farmers as soon as pulled, at so much per ton for the raw material. This would save the farmers all the extra labour that would necessarily be incurred in the steeping, spreading, turning, trying, &c., and as the flax would come in about the busiest season, and the seasons in this country being so short, I believe the extra labour likely to be incurred would be the greatest drawback to its introduction here. As far as Schenk's system is concerned, I have seen it tested, and have no hesitation in saying that it would pay as a commercial speculation. Were a Company formed in the town or country they might get up machinery for the manufacture of flax through every process, from the raw material to the finest linen; rendering us in a few years entirely independent of the cotton of the Southern States.—J. W. M.—*Woodstock Times*.

### Products of the Hemp Plant—(*Cannabis Sativa*.)

The hemp plant is known chiefly in this country on account of the valuable fibre it affords, which is in such constant use in the manufacture of cord, ropes, &c. Although its fibre is of the greatest value to us, still its other products are equally valuable to the natives of tropical climates. For example, in the East it is cultivated entirely on account of its narcotic resin, which is spontaneously secreted in all warm climates. In cooler temperatures it is grown exclusively for the sake of its fibre, as in Russia, Prussia, Spain, Italy, &c. It grows wild in temperate Asia and in Northern India.

Hemp appears to have been known from a very remote period, the first mention of it being made in the first book of Herodotus (C.202) where he says: "The Scythians never washed any part of their bodies excepting their heads, and accordingly purified themselves with an intoxicating kind of smoke, which seems to be somewhat analogous to the smoke of tobacco. Having first washed and thoroughly cleansed their heads, they made a tent by stretching thick

woollen cloths over three fixed sticks in the ground and inclining towards each other. They next placed a vessel full of red hot stones in the centre of the tent, and crept round it, whilst the tent covering was kept very close and almost air-tight. They then threw hemp seed on the hot stones, and a smoke and steam soon arose, which was denser than the hottest vapour bath, and the intoxicated Scythians would cry and shout at the top of their voices, from the excitement and exhilaration produced by this overpowering process." It is mentioned again in another book of the same author, where he speaks of the Scythians having "a sort of hemp very much like flax," growing "both spontaneously and from cultivation," and of garments being made from it by the Heracians "very like linen." It is also spoken of by Pliny, who says the plant was well known to the Romans. Mention is also made by the writer of some medicinal properties reputed to belong to it. Thus we see that the plant was well known to the Greeks and Romans; but the Hebrews and Egyptians seem to have been unacquainted with it. At the present time it is grown to a great extent in Russia, wholly on account of its fibre, from which country we received, in 1860, 597,610 cwt. We also find it cultivated in some parts of India, Africa, and China, and also to a small extent in the United States and Canada. It grows well in England, and is cultivated largely in some counties, as Suffolk, Yorkshire, Lincolnshire, &c. The finest kind is obtained from Italy, though in small quantities; it is known as "Italian Garden Hemp," being raised by spade culture. This is sometimes eight or nine feet long, and is used for sail-cloth as well as for the finer kinds of cordage. The mode of preparing hemp much resembles that employed in the preparation of flax. Its values and uses are so well known that it is needless to mention them here. For its narcotic and resinous properties, it is exclusively cultivated in some parts of Africa and India. The value of the fibre of hemp grown in those countries seem greatly diminished, while the resin-producing properties of the plant appear much enhanced by growth in tropical climes. This resin, called in India "Churrus," is collected in the following curious manner: Men are clad in leather dresses, and sent into the hemp field, where they brush about amongst the plants in a furious manner. The soft resin, by this means, adheres to their dresses, and is afterwards scraped off and made into balls. The leathern costume is said to be dispensed with in Nepal, and the resin collected on the bare skins of the coolies. In Persia it is collected by submitting the plants to pressure between coarse cloths, which are subsequently scraped, and the resin melted in pots with the aid of warm water. A finer kind of this resin called waxen churrus, or "momea," is collected by hand. This fetches a high price, nearly double that of the ordinary kind, which usually

sells at from five to six rupees the seer. Churrus is of a dull greyish brown color, with little or no smell, and is usually met with in cakes from two to three inches long, somewhat in the shape of a lemon. It is used in medicine in India, and is reported to have been successfully employed in tetanus, though its application in this country, for the same purpose, has failed to give satisfactory results. Its intoxicating effects, as shown by Dr. O'Shaughnessy, are most remarkable.

Hemp enters into India commerce in other forms besides Churrus. Gunjah, or Ganjah, is found in the Calcutta bazaars, and is used chiefly for smoking. It consists of the plants themselves, with the leaves and inflorescence attached, and upon which the resin is left adhering. It is made up in bundles from three to four feet long, containing about twenty plants. These are flattened by pressure, and their colour is of a greenish brown, while there is present a heavy aromatic odour. It is smoked in a similar manner to tobacco, and it is said that its continued use brings on severe asthma. In Africa it is known as "Djamba," and is found in the markets packed in slips of palm leaf or husks of maize, generally about two feet long, tied at top and bottom, and at intervals of about an inch or inch and a half throughout the whole length of the case. When required for use, one of these divisions is cut through, which is sufficient for one pipe. The packages are sometimes smaller, and the "charges" not much larger than a marble. The "Hasheesh," or "Hasshisch," of the Arabs appears to differ from Gunjah in this peculiarity, that it is composed of the tops and other tender parts of the plants after the flowering period. They use it in a variety of ways other than smoking, for which purpose alone they have many modes of preparing it. They make it into an electuary, with the addition of dates, or figs and honey, and sometimes cloves, cinnamon, or musk, boiled in butter, or oil and water: the filtered product is used in pastry. "Bhang," "Sidhee," or "Subjee," is composed of the larger leaves and capsules with a very small quantity of resin. This, like Gunjah, is sold in the Indian bazaars. Its intoxicating properties are not so great; indeed, it is not applied to the same use; but being mixed with water and other additions, is formed into a drink called "Subzee," which is reported to be highly conducive to health. A stimulating infusion is prepared from the plant in Scinde, which is said to promote appetite, and is in great repute among the upper classes. The fruits of the hemp plant, which are usually known as hemp seed, are oleaginous and demulcent, but appear to be devoid of any narcotic principle. Their chief use is for feeding cage-birds. A serviceable oil is expressed from them which is used for mixing paints, burning in lamps, and also in the manufacture of soft soap.—*The Technologist for January.*

### Stock Feeding.

BY CUTHBERT W. JOHNSON, ESQ., F. R. S.

At a season when the feeding of stock is so generally engaging the attention of the readers of this magazine, we may usefully gather together, and carefully consider a few recent efforts to render that feeding more profitable. The health of our stock is a primary consideration. The common diseases of sheep when feeding off turnips is one very important question. The Highland Society of Scotland have lately awarded a premium to Mr. Hugh Borthwick, of Traquair-Knowes, for his essay on those too commonly fatal diseases—(*Trans. High. Society*, 1861, p. 127.) The disease of which he chiefly treats, are braxy, pluerio-pneumonia, louping-ill, and sturdy. The means of *prevention* of these diseases, which he considers the most successful, are for braxy, (which he thinks can be almost totally prevented by good management,) by putting the sheep on to the turnips gradually, two hours the first day, three the second, and so on for the course of a week; afterwards, if well sheltered, by closely confining them on the turnips, and supplying them with hay and straw, and in the importance of this change of food, every reader will concur. Another great object is, to have the roots consumed as free from dirt as possible; to this end the sheep should always be shifted to a fresh lot before the *shells* are eaten too bare, especially if the soil is damp. When the hoar frost is on the turnips, the flock ought not to be shifted until it is off the shaw. The surface of the frozen leaves of the turnips are then covered with so much frozen water as to be injurious to the sheep. Of pluerio-pneumonia, the conclusion to which Mr. Borthwick arrives is, that it is difficult to prevent this disease on sheep fed on turnips, especially in old ewes brought from pastoral districts. He is of opinion, that there is in some sheep an hereditary predisposition to this disease—a conclusion which he supports by several instances; he advises that when sheep are suspected of being tainted with it, they should have hay and a little bruised corn along with the turnips to prevent them from scouring. He adds, "I have tried to fatten sixteen sheep affected with pluerio-pneumonia within the last three years, on this kind of food, thirteen of which fed well, the other three died."

For louping-ill, or staggers, which frequently breaks out among hogs fed on turnips, the only preventive Mr. Borthwick deems effectual is, by keeping the turnips clean, giving the sheep a variety of food, hay if it can be had, and shelter at night, if the weather is stormy. He is of opinion that hogs had better be driven a mile every night to obtain shelter, than allowed to lie all night exposed to wind and rain.

The prevention of sturdy in sheep, Mr. Borthwick considers best accomplished by attention to their food; he tells us that on the farm of Tra-

quair-Knowes, when the hogs were kept on turnips alone, the cases of sturdy were great. One year especially, there were as many as five to the score affected; whereas, for the last two years, when hay, and rape cake were given along with the turnips, and shelter attended to, the cases of sturdy have not been more than one in a hundred. And yet, during these two years, the lambs were not better nursed than in other years, when sturdy prevailed to such an extent.

The ill-effects of the sheep being compelled to eat dirt with their turnips is hardly so well understood as is desirable. The dirt in some cases, as in braxy, accumulates to such an extent, that it may be taken out of the animals in handfuls. In acute cases of staggers, the clay, or dirt, sometimes mixed with wool, is found in the animal in round balls.

On the *prevention* of the rot in sheep, Professor Simonds not long since addressed the Council of the Royal Agricultural Society. He then told his hearers, "This year I had a number of sheep, and foresaw what was coming. I warned some of my neighbors, that we should have a great deal of rot this year, and I thought I would attempt, as far as my own sheep were concerned to save them. What did I do? The sheep were on wet meadows, nearly up to the fetlock joints every day, and nobody could avoid it. But at midsummer I began to feed the lambs and sheep with corn and nitrogenized food, giving them with every meal, a small quantity of salt. I continued that plan during the whole summer and autumn, and I have the satisfaction of saying that I do not believe at the present time that I have one of those lambs affected by the rot. I kept killing them week by week to watch their progress. And here I may observe that long-continued wet weather is very prejudicial to the sheep in another way. I refer now to the so called water rot. What was the state of the liver of these animals at midsummer? There were no flukes or anything of the kind, but the liver was streaked here and there with white lines, and generally pallid. This was for the want of nitrogenized matter. The bile-cells were blanched; the liver had become structurally diseased, and as such it was a good nidus for these entozoa to inhabit. Not only, however, did this simple treatment prevent the entozoa, but it brought about a healthy state of the liver; for in the course of a month or so, I found that the organ resumed its natural colour, and consistence; so that if we commence at midsummer, and continue this treatment through the entire dangerous period of a wet season, we may do a great deal in the prevention of the rot; and I may go further, and say, that even on the farms that have what are all called rotten pastures, on which the sheep are placed, the animals might be preserved to a very considerable extent, simply by giving nitrogenized food and salt, to destroy these creatures within the stomach, and prevent their final change, and alternating with

the salt a tonic invigorating agent, such as the sulphate of iron.

The result of all these researches on the diseases of sheep tend in the same direction, viz., that by attention to the comfort and food of the sheep, many diseases of the sheep are prevented; and no one with whom we have to do will doubt the advantage of thus preventing diseases, not only difficult to cure, but in animals commonly of too little value to repay the cost of medical attendance.

These remarks need not be confined to one variety of our domestic animals; our oxen and our horses, equally benefit by attention to their comfort and their food; and be it remembered, the cost of that food, given with the primary intention of keeping the stock free from disease, need not be regarded as an outlay for which there is no other return. The increase of their weight, the improved quality of their manure, must both be put against the cost of the purchased artificial food. This was lately very fairly put by Mr. Owen Wallis, of Overstone Grange, when addressing the members of the Central Farmer's Club, on the very important question of "the increased feeding of stock on pasture land, in spring, summer, and autumn." The means he suggests are—a better system of management of pastures, and to return to the six course rotation. He said, "I remember when the artificial grasses were very generally grazed for two years, and some for even three. There was therefore, one third of the light arable soils on farms so managed in pasture; and a much greater number of cattle and sheep were then kept upon them than there are at the present day. I have, on former occasions, when addressing the members of this Club, advocated a return to the six course rotation; and the increased value of both store and fat stock is an additional reason for its adoption. I have long been of opinion that more stock may be produced and more corn grown at a less cost by that system than by any other." Then he advises the use of oilcake when cattle are on the pastures, giving the stock the cakes in troughs in the open field, or, what is better, in sheds. As to the quantity given, Mr. Wallis adds, "I commence with 4lbs. per day, and finish with 6lbs., giving on an average 5lbs. per day. If this continued for six weeks, it will amount to 15 stones per head, which at about the average price of cake during the summer will not exceed 20s. We know from our experience that between a ripe bullock and one that is not well up to the mark, there is commonly a difference of more than double that sum in their respective prices, supposing they are equal in size. If, therefore, by an outlay of £1 we receive £2, the investment is a profitable one. But supposing it to be rather less than this, we must not forget the extra number of beasts that can be so fed on the same quantity of land; and the rent, rates, and taxes being the same in both cases, a further additional

profit is thus obtained, to say nothing of the rapid improvement of the soil."

Admitting then the advantage of giving extra food to our stock, another enquiry seems to follow closely upon that conclusion, viz., the comparative profit derivable from the use of different varieties of artificial food. Now on this very important question some carefully conducted experiments with different kinds of artificial food, both for cattle and sheep, are reported in the prize essay of Mr. W. Horn, of Brome Hall, in Norfolk (*Trans. High. Society*, 1861, p. 533). Six bullocks, bred from Ayrshire cows by a Shorthorn bull, in lots of two each, were fed in boxes from Dec. 10, 1859, to April 10, 1860. Five pounds of the artificial food were given to each bullock per day, with 99lbs. of roots, swedes, and mangolds, and 6lbs. of meadow hay; the result was as follows:—

| Lots.                            | LIVE WEIGHT. |          |      | GAIN. |
|----------------------------------|--------------|----------|------|-------|
|                                  | Dec. 10.     | Apr. 10. |      |       |
|                                  | Lbs.         | Lbs.     | Lbs. |       |
| 1. Bruised Linseed . . . .       | 2,716        | 3,434    | 718  |       |
| 2. Ground wheat & barley . . . . | 2,688        | 3,347    | 669  |       |
| 3. Oilcake . . . . .             | 2,754        | 3,391    | 637  |       |

At the same time, seven lots of Cotswold sheep, in pens of eight each, were fed under a well-ventilated shed—for the first month, on cut swedes thrice a day; the second, on swedes and mangolds; for the last two months, on mangolds alone, with 1lb. of meadow hay each per day, which they had throughout;  $3\frac{1}{4}$  lb. each sheep. The other pens, the same money value of the other food, oilcake being £10 10s. per ton, rapecake £6 10s, cotton-cake £6 10s., locust or carob beans £6 10s., peas £9 10s., linseed £13 bruised barley £8. It was found that each lot consumed nearly 120lbs. of roots and 8lbs. of meadow hay per day. The results of these experiments—which, says Mr. Horn, received every attention, in order to elicit the truth—were as follows:

| PEN.                        | LIVE WEIGHT. |          |      | GAIN. |
|-----------------------------|--------------|----------|------|-------|
|                             | Dec. 10.     | Apr. 10. |      |       |
|                             | Lbs.         | Lbs.     | Lbs. |       |
| 1. Rapecake . . . . .       | 876          | 1,235    | 359  |       |
| 2. Cotton-cake . . . . .    | 890          | 1,215    | 325  |       |
| 3. Oilcake . . . . .        | 884          | 1,297    | 413  |       |
| 4. Locusts . . . . .        | 860          | 1,222    | 362  |       |
| 5. Peas . . . . .           | 890          | 1,273    | 383  |       |
| 6. Linseed . . . . .        | 876          | 1,263    | 387  |       |
| 7. Bruised barley . . . . . | 894          | 1,231    | 347  |       |

Another mode of putting the result of far more lengthened and elaborate experiments on the same subject, is that of Mr. T. B. Lawes. (*Jour. Roy. Ag. Soc.*, vol. xxii., p. 214) that

|                                        |                                         | lb. oz. |  |
|----------------------------------------|-----------------------------------------|---------|--|
| Oxen consume, to produce 1lb. increase | in live weight, of the DRY substance of | 13 0    |  |
|                                        | the food consumed. . . . .              |         |  |
| Sheep, ditto, ditto . . . . .          |                                         | 9 2     |  |
| Pigs, ditto, ditto . . . . .           |                                         | 4 8     |  |

Thus, when liberally fed under cover, in proportion to a given live weight, within a given time, sheep will consume about  $1\frac{1}{4}$ , and pigs about  $2\frac{1}{4}$  times as much dry substance of their food (that is, of food entirely free from water) as oxen. Oxen should yield per week about 1, sheep about  $1\frac{3}{4}$ , and pigs 5 to 6 per cent. of their weight of increase.

These comparative results Mr. Lawes has illustrated by referring to the anatomical construction of the ox, the sheep, and the pig. He shows (*ibid.*, p. 215) that, in proportion to the weight of the body, oxen have considerably more of stomach and contents than sheep, and sheep considerably more than pigs. On the other hand, pigs have a considerably larger proportion of intestines and contents than sheep, and sheep more than oxen. But of stomachs and intestines, and their respective contents, taken together, oxen have a larger proportion than sheep, and sheep a larger proportion than pigs. Again, the dry substances of the mixed food of oxen contains a larger proportion of woody fibre than that of sheep, and that of sheep considerably more than that of pigs.

The results recorded in the last little table of Mr. Lawes, which I have just given, are quite in conformity with the facts he has stated with regard to the comparative structure of the different animals; and the comparative character of their respective foods. Thus, oxen, with the most bulky and (weight for weight) least nutritious food, have the largest proportion of stomach, and the least of intestinal surface for the absorption of nutritious matter. Now, oxen give also the least proportion of increase for a given amount of the dry substance of food. Sheep come next in order to oxen in these respects. The dry substance of the food of the pig is in much the largest proportion digestible, and available for assimilation and respiration. He has also much the largest proportion of intestinal surface for the absorption of nutritious matter; and he yields much the most increase for a given amount of a dry substance of food. Calculation further shows that that oxen expend in respiration the most, sheep considerably less, and pigs much the least of the dry substance of food, in proportion to a given amount of fattening increase yielded.

In calculating, then, the profit or loss derived from the use of artificial food, several branches of the inquiry must be taken into our consideration. It is generally understood by my readers that oilcake is not directly repaid by the increased market value of the animal; but then, as I have endeavoured to show, the greater health and the largely improved value of the manure must be included in the estimate. To this question Mr. P. N. Frere (*Jor. Roy. Ag. Soc.*, vol. xxi., p. 219), has devoted considerable attention, and the results of his experiments also confirm the ordinary conclusion, that stock do not pay, at least directly, for the artificial food bestowed upon them.

On the use of straw as food very considerable difference of opinion prevails. This question forms a portion of the valuable prize essay of Mr. N. Evershed, on the "Proper uses of Straw on a farm" (*ibid.*, vol. xxi., p. 158). He arrives, as a practical man, at certain conclusions, in which most of my readers will concur. He is of opinion that although it is a common plan, in grazing districts, where roots are scarce, to feed store cattle on about 30lbs. of straw and 3lbs. of bean-meal per day, yet that they do better with roots instead of meal, even where the supply of roots does not exceed half a hundred-weight per head daily. Cattle wintered on straw and meal, are certainly, as he remarks, apt to become "hide-bound," with staring coats.

The average amount of straw per acre Mr. Frere calculates to be  $2\frac{1}{2}$  tons, or 250 tons from 4 cwt. of straw enter into the composition of a ton of farm-yard manure, the remainder being 10 cwt. of water and 6 cwt. of excrement. The consumption of straw chaff by a cart-horse, he places at rather more than a ton per annum; cattle 21 cwt.; for the sheep on a farm of 400 acres he assigns 8 tons of straw chaff yearly. On an arable farm of 400 acres Mr. Evershed calculates that there is required for the yearly fodder of fifty head of large stock more than 50 tons of straw; for sheep, 8 tons; for storing roots, foundation of stacks, &c., about 5 tons—total 63 tons of straw.

It is now some little time since I first suggested the admixture with the chaff, cut turnips, and other ordinary food of sheep, certain more stimulating substances, and I did this from noting the natural habits of the wild sheep, when browsing on the mountains on which it is found, its love of elevated healthy pastures, its consumption of aromatic plants. On the Southdowns of England the same remark may be made. On these upland pastures we find the juniper, the wild thyme, and other indigenous aromatic plants, an the grazing ground of some of our noblest and most prosperous flocks.

It is not to such admixtures that we must attribute the asserted success of some of the new cattle foods? And might not the number of these aromatic, stimulating additions to the ordinary food of our stock be increased by other and cheaper native and foreign substances? Are there not to be obtained in newly explored African districts, for instance, the oil seeds of equatorial plants, that would very profitably warm the cold cut roots and the chaff on which we compel our flocks and our herds to feed? It is only by studying Nature's great book that we can ever hope to advance in this important direction. But what we have done in this way, how little of nature's teachings we have infused into our stock feeding, let our mountain sheep fleeing of turnips, and our pure-air loving oxen, fattening in a box over a deep bed of dung, give them unanswerable testimony.—*Farmer's Magazine.*

### Ergotised Wheat.

The following account of what followed the use of Spurred or Ergotised wheat is taken from that excellent work, *Sowerby's Grasses of Great Britain*; and will serve as a warning to every one, that all diseased grain, of whatever kind, is to be dreaded; and especially that it is a great mistake to imagine that the spurs of Rye are alone capable of producing fearful consequences:—

"Wheat is no less liable than Rye, and, indeed, all kinds of corn and cultivated vegetables, to disorders associated with the developement of minute species of fungi; and though ergot is less frequent in its attacks upon it than is the case with the last mentioned grain, several other equally destructive members of the class, known by the more familiar names of smut, rust, and mildew, seem always to avail themselves of every opportunity, that weakness engendered by adverse seasons or circumstances presents. Straw, foliage, husk, and grain afford in turn a subject for their insidious depredations, which are always more or less injurious, not to the quantity alone or the crop, but to its nutritive and healthful quality. Instances of this deterioration are shown in the analysis of our agricultural chemists, as in that of blighted Wheat, grown in 1804, by Sir H. Davy, which presented the average quantity of 955 parts of nutritive matter in the 1000 reduced to 650, while a sample of mildewed wheat, in 1806, yielded only 210 in the 1000. The consequence of using such Wheat as food, especially the last mentioned, would, of course, be a step toward starvation, even though no greater evil resulted. It is, however, well known to be highly prejudicial to health and the higher standard of living among the poorer classes of our population, compared with these of some continental countries, is the only cause of their exemption from the dreadful disease mentioned above as resulting from the use of bad Rye. That such disease might occasionally prevail among them here from similar causes, under a more restricted form of diet, is evident from a record in the Philosophical Transactions for the year 1762. The case in question occurred in the village of Wallisham, about 15 or 16 miles from Bury St. Edmund's, Suffolk, and the report of it was forwarded to the Royal Society by Dr. Wollaston, attested by the Rev. Mr. Bone, the curate of the parish, and is abridged as follows:—Some of the Wheat belonging to a farmer in the neighbourhood, being laid or beaten down by bad weather, and the grain much damaged in consequence, was collected and threshed apart from the remainder. Being unfit for the market, it was sold at a low price to any of the farm-laborers, and other people of the village who might be inclined to purchase. The sale

of this corn commenced about Christmas, and to one poor family, whose chief, or possibly sole support it was for some time, the result was most alarming and unparalleled. It appears that the consumption of the clog-wheat or rivets, as it is termed, by the father, mother, and five children, was about two bushels in the fortnight; the same being eaten in the form of bread and puddings, both of them very indifferent in quality. But to poverty, cheapness and sufficiency of food are always irresistible inducements, and this unwholesome fare was continued, without intermission, until the mother and her children were attacked, within a very few days of each other, with gangrenous ergotism. The first indication of the disease, intense pains in the lower limbs, occurred on the 10th of January, which were probably mistaken for rheumatism; and when these subsided, within the course of the week, numbness and insensibility of the parts succeeded, terminating in mortification. The condition of the family at the time Dr. Wollaston made his report to the Society is here subjoined:—

'Mary, the mother, aged 40. Right foot off at the ankle; left leg mortified, a mere bone, but not rot off.

'Elizabeth, aged 13. Both legs off below the knees.

'Sarah, aged 10. One foot off at the ankle.

'Robert, aged 8, both legs off below the knees.

'An infant, aged 4 months. Dead.

'The father was not attacked until about a fortnight after his wife and children, and in a slighter degree. In him the pain was confined to two fingers of his right hand, which turned blackish, and withered. Another labouring man, in the same parish, who had eaten of this bread, suffered from numbness in both his hands for about a month. They were constantly cold, and his finger ends peeled; one thumb, he says, remains without any sensation.'

In several instances, where bread made from the same corn was eaten in the farmer's own family, as well as by other persons, no prejudicial effects were noticed, probably in consequence of such bread being only occasionally used, and as an adjunct to other wholesome food. The nature of the disease with which the Wheat was affected, in this lamentable case, does not appear to have been ascertained; but the circumstances are well authenticated, and were in my boyhood, the early part of the present century, the subject of local tradition in the part of the county of Suffolk in which they took place. It is possible that the fatality attendant upon the use of the damaged grain, in the unfortunate family above mentioned, arose quite as much from the absolute deficiency of proper nourishment, as from the alleged poisonous quality of the mildewed fungus; but, with such examples before us, too great caution cannot be enforced regarding the use of grain or flour of suspicious character."

### To Avoid Running Out of Hay.

Every farmer naturally has an aversion to running out of hay in spring before grass comes. No one desires to buy that which he ought to have raised, to keep his cattle from starving; and the only alternative, when short of fodder, viz., placing them on short allowance, is still worse. The farmer should know before he enters winter whether he has enough feed for all his domestic animals.

To ascertain this, many resort to past experience, determining as nearly as they can, by guess—often by a very vague kind of guessing. Those who have kept careful record of the number of tons consumed by a given herd of cattle, or a certain number of horses, may determine more nearly. Where the cattle and horses have been weighed, and the aggregate weight of the herd thus determined, the estimate may be made with considerable accuracy. Some animals eat more than others for the same weight; a greater difference is occasioned by the severity or mildness of the weather, or the degree of shelter given from the cold; but as a general rule, a horse should have three per cent of his weight daily in food (hay or grain,) and cattle, which digest better, two and a half per cent. If the farmer has ascertained the number of tons of fodder he has deposited in his barn, he may now, if he understands arithmetic, determine pretty nearly, how his hay is likely to run, before grass time.

If he has no record of the amount of his hay, he may determine, very nearly, by measuring. First, by finding the length, breadth, and depth of the hay, he at once knows the number of cubic feet. Good solid timothy; the average of a bay 12 or 15 feet deep, will weigh a ton, to about 500 cubic feet. If the hay is clover, it will require 600 or 650 for a ton; and if the hay is only 5 or 6 feet deep, add one-sixth more.

After determining the number of tons, and the whole weight of all his animals, he may at once know if he has enough. The result will, however, be considerably modified by causes which he has more or less at his control. Regularity in feeding will have its influence; good feeding racks will prevent much waste; and comfortable shelter will save many tons to every large herd. A skillful farmer informed us, that formerly when he had just erected a fine new barn, with ample shelter of the best kind, he had learned, as he thought, according to his usual estimate, that he would have to buy hay to complete the wintering of his animals; but on trying his new sheds and stables, so great was the saving actually effected, that he had several tons the next spring to spare.—*Country Gentleman*.

### The Real Value of Artificial Cattle Foods

Professor Anderson, Chemist to the Highland Society, has carefully analyzed the principal

cattle condiments which have recently obtained great notoriety. In the new number of the "Transactions of the Society," he gives the ingredients of each sample submitted to analysis, and thus sums up his opinion of them:—

"The examination of these analyses shows that there is a very close general resemblance among the samples. Whatever difference may exist in the nature of the ingredients or the proportion in which they are mixed, there is but little in their nutritive value. They are, in fact, all composed of ordinary feeding grains, with the addition of certain aromatic or bitter substances, forming but a small portion of the whole. The methods of chemical analysis which enable us to state how much sugar or albuminous compounds any mixture may contain, do not admit of our determining the proportions of the various seeds or other substances mixed together; nor is this a matter of any moment as far as nutritive value is concerned, for it is immaterial whether these particular elements are derived from one or other grain. It is their combined effect which is of importance. Looking, therefore, at these foods merely in a nutritive point of view, it must be unhesitatingly asserted that they have nothing to recommend them. They are, in fact, inferior in this respect to many of the simple foods in common use—such for example, as linseed or oil-cake. Neither have they any claim to be considered as "concentrated" foods in the sense in which we speak of concentrated manure. There has been no removal of the innutritious matter, the water being nearly the same as in most seeds, and the woody fibre exceeding in amount that found in the common grains or in oil-cake. Nor can this excite any surprise, for they are all mixtures of those substances with aromatic seeds or roots, which are all much richer in woody fibre than the nutritive grains.

"The presence of aromatic or bitter matters is, therefore, the sole peculiarity of these cattle foods; and it is obvious that these substances ought to produce any effect of which they are capable, just as well if they added to the ordinary food of the cattle, as if they be mixed by a manufacturer with other substances before being sold to the farmer.

"It has been already remarked that the effect attributed to aromatics by the makers of these foods is, in the last degree problematical, and unsupported by any well ascertained facts; and their assertions must go for nothing, unless they are prepared to support them by experiments which shall be satisfactory to experienced feeders. As matters at present stand, they must be judged of on the same principles as those used in estimating any other food, and in this respect they cannot be ranked very high. If they possess any special action, it is self-evident that it must belong to the aromatic or bitter substances they contain; and if the makers wish to satisfy

the farmer on these points, they ought to put it in his power to use the aromatics alone, and allow him to mix them with such foods as he may choose. This course however, will by no means suit their purpose. At present they take carob beans, Indian corn, and other substances, costing £8 to £9 per ton, which are mixed with a small quantity (about 10 per cent) of some aromatic, costing perhaps £20 or £25 per ton, and the mixture so produced, at a cost of perhaps £10 or £11 per ton, is sold to the farmer at £30. It is quite obvious that as long as a manufacturer can sell the article he produces at a price approaching three times its intrinsic value, he will not trouble himself to inquire into the exact facts of the case, and will be satisfied with denying, in place of refuting, the statements of scientific men. The opinions I have expressed regarding these feeding-stuffs are in complete harmony with those entertained by all agricultural chemists. They have already been often expressed, and their accuracy strenuously denied by the concentrated-food makers, and they will no doubt be again denied, but they will not be disproved by them. If the manufacturers really desire to satisfy the agricultural community, the proper course would be for them to submit their foods to some farmers of experience, in whose judgment full confidence can be placed, and agree to stand or fall by the result. From this ordeal they will doubtless shrink; and as long as they do so, they must be content to bear the imputation of trading on the credulity of the farmer, and selling him an article at three times its real value.

"I have not hesitated to express thus distinctly the opinions I entertain, because this is a subject on which science can speak with no doubtful voice. It is not a question in regard to which there can be any difficulties, but is one of comparing the results of analyses with those of other and well-known foods; and before a minute examination the alleged "discoveries" of the inventors of these substances vanish into thin air, or rather revolve themselves into the art of making the farmer pay dear for a cheap article."

### Meeting of the Board of Agriculture.

The Board of Agriculture met at their Rooms, 188 King Street West, Toronto, pursuant to call of the President, on the 29th ult., January, 1862, at 3, p. m..

Present: Messrs. E. W. Thomson, President; Hon. G. Alexander, Hon. D. Christie, Hon. H. Ruttan, R. L. Denison, F. W. Stone, President of the Agricultural Association; Professor Buckland.

The Minutes of last Meeting were read and confirmed.

After some informal conversation in reference to the objects of the Public Meeting called for to-morrow, 30th inst., to take into consideration the amendments desirable to be made in the Agricultural Statute, the following mentioned communications were submitted:—

Letters from several Agricultural and Horticultural Societies, naming the delegates to the public meeting on the 30th inst.

A letter from Mr. F. Shanly, tenant of the house and premises of the Experimental Farm, asking for a remission of rent, to the amount of \$211.60, on account of certain improvements stated to have been made by him on the said premises.

A special report upon some Shropshire Down Sheep, lately imported by Mr. Geo. Miller, of Markham, and exhibited by him at the Provincial Exhibition at London last year, suggesting the awarding of a special prize to the same.

From Mr. Chamberlin, Montreal, Secretary to the International Exhibition Commission to take place at London, England, this year, soliciting the co-operation of the Board in procuring a collection of cereals and other farm produce for the said Exhibition.

From Mr. Alex. Campbell, London, late contractor for the Provincial Exhibition Buildings at that city, asking for payment of an account of \$595.39, for work executed upon the Exhibition Grounds beyond that for which he had been paid by the local committee.

Two letters from J. H. Flock, Esq., Solicitor, London, on behalf of Mr. Campbell, requesting payment of the above claim.

From a Committee of the West Elgin Agricultural Society, complaining of proceedings which had taken place at the Annual Meeting of that Society, on the ground that a large number of persons, who, the Committee believed, were not legally members, had taken part in the election of office-bearers, and overruled the legally constituted members of the Society, and asking for the advice of the Board in the premises.

## OF THE BOARD OF AGRICULTURE.

Ordered—In reference to the Shrophshire Down Sheep, exhibited by Mr. Miller at the London Provincial Exhibition, that the prizes remain as awarded by the Committee of Judges at London.

Moved by Hon. Mr. Alexander, seconded by Hon. Mr. Christie, and

*Resolved*,—That Professor Buckland and the Secretary be requested to republish, as an extra of the next number of the *Agriculturist*, a small manual giving to the farmers information respecting the culture and after management of flax, to be distributed in those counties where the farmers are desirous of introducing that product.

The Board then adjourned to 10 a.m., to-morrow.

The Board resumed according to adjournment.

Present, the same members as yesterday.

Major Campbell, a member of the Board of Agriculture of Lower Canada was also present.

The Minutes of yesterday were read and approved.

Some conversation took place on the nature of the changes desirable to be made in the *Agricultural Statute*. Major Campbell, on request of the Board, gave some explanations as to the details of the Bill which he had introduced into Parliament.

The following gentlemen were nominated to form the nucleus of the Local Committee for the Provincial Exhibition of this year, at Toronto, viz.:—F. W. Jarvis, Esq., Sheriff of York and Peel; J. P. Wheler, Esq., Warden of the Counties; J. G. Bowes, Esq., Mayor of the City of Toronto; James Beachall, Esq., President of the Toronto Electoral Division Agricultural Society; Hon. G. W. Allan, President of the Toronto Horticultural Society.

The Secretary was instructed to request these gentlemen to meet at the Board Rooms on February 8th proximo, at noon, to consider the preliminary arrangements connected with the approaching Exhibition.

On motion of Professor Buckland it was Resolved that the Board of Arts and Manufacturers be requested to *revise* the Prize List of the Arts Department of the Exhibition, in the same manner as they had done last year.

The Board then adjourned in order to attend the Public Meeting to be held at noon, this day, in reference to the *Agricultural Statute*.

### PUBLIC MEETING.

The Public Meeting, called by circular, in accordance with the resolution passed at the annual meeting of the Agricultural Association at London, in September last, a copy of which circular appears in the *Agriculturist* of 1st ult., assembled in the lecture room of the Mechanics' Institute, Toronto, on the 1st ult.,

at noon. The attendance was large and of a highly influential character.

The following gentlemen were present:

#### DELEGATES FROM COUNTY AND ELECTORAL DIVISION AGRICULTURAL SOCIETIES.

#### MEMBERS OF THE BOARD OF AGRICULTURE.

E. W. Thomson, R. L. Denison, Hon. D. Christie, Hon. G. Alexander, Hon. H. Rutlan, F. W. Stone, Professor Buckland.

#### MEMBERS OF THE BOARD OF ARTS AND MANUFACTURES.

Dr. Beatty, W. H. Sheppard, W. Edwards, Rice Lewis, Dr. Craigie, T. Sheldrick, H. E. Clarke.

Lower Canada Board of Agriculture, Major Campbell.

The delegates having taken their seats, Colonel Thomson, President of the Board of Agriculture rose and explained that this meeting having been called in accordance with a resolution of the Agricultural Association, was properly a meeting of Delegates from the County Agricultural Societies, and the members of the Board of Agriculture did not propose to take part in the proceedings unless called upon to do so. They would however be present to give any explanations that might be asked for.

It was then moved by Colonel Saunders, seconded by Mr. Cooley, that Colonel Thomson be requested to take the chair.—Carried.

Moved by Mr. Johnson, seconded by Mr. Beadle, that Mr. Hugh C. Thomson be requested to act as Secretary.—Carried.

Moved by Mr. Blair, seconded by Mr. Foott, that the members of the Board of Agriculture present be requested to take a share in the deliberations of the meeting.—Carried.

On motion, Major Campbell, of Lower Canada, was also requested to take part in the proceedings.

[For the sketches of speeches which follow, we are principally indebted to the report of the Toronto *Globe* newspaper.]

The Chairman, in opening the proceedings, said the object of the meeting was to take into consideration a Bill which passed the House of Assembly last year, but which was rejected in the Upper House. This Bill did away with the Agricultural Association *in toto*; it deprived the people of the different agricultural societies of the privilege of sending up delegates to the annual meeting for the selection of officers and for the selection of a place at which to hold the next annual fair.—The Bill entirely did away with this and left the power in the hands of a Board of Agriculture to be elected by the agricultural districts as proposed by the Bill. It entirely tomahawked the old association, which had been in existence sixteen years, which had worked to the approval of the public, and had been admired by visitors from all parts of the world. If the meeting thought another mode of electing the members of the Board of Agriculture was preferable to that now pursued, they would now have an opportunity of making their views known.

Hon. David Christie wished to correct a wrong impression which perhaps might be made by a remark of the Chairman. He [Mr. Christie,] referred to that portion of his speech relating to the rejection of the bill by the Upper House. It was not rejected by the Upper House—it was referred to a committee and the committee did not report. The reason was that Messrs Alexander and Allan, with himself (Mr. Christie,) felt that it would be very unwise to give their assent to the changes proposed in the absence of a single

petition; for there was not a single petition presented in favor of the bill. It was, therefore, laid over for the purpose of ascertaining what the wishes of the people of Upper Canada were in reference to it.

Hon. Mr. Alexander endorsed Mr. Christie's explanation.

Major Campbell said, as he was a foster-parent of the bill which it was now proposed to discuss, he would with the leave of the Convention explain its bearings.

He appeared at the meeting as a representative of the Board of Agriculture of Lower Canada. At its last meeting a resolution was passed deputing two of its members, the President (Hon. L. V. Sicotte) and himself, to attend this meeting to give any explanations connected with this bill. The President was unwell and unable to attend. He (Major Campbell) was therefore left the sole representative of Lower Canada. It was felt in the Eastern portion of the Province that sufficient interest was not taken in the Board of Agriculture, and they came to the conclusion, that if its organization was somewhat altered by dividing the country into districts, and allowing each district to send a member, greater interest would be felt by the people. At the third session of the last Parliament, he (Major Campbell) obtained a committee to enquire into the matter. It was composed of members from Upper Canada as well as from Lower Canada. The committee sat for a considerable time, and at last made a report upon which his bill was based. By the time that was done the session came to an end. The succeeding session—the last—he (Major Campbell) immediately upon taking his seat, introduced the bill and it was again referred. The bill which was passed by the Lower House was the result of the deliberations of the Committee. It differed in some respect from the *projet de loi* which he (Major Campbell) had submitted. At the present moment the Board of Agriculture was composed of eight members, four retiring each year who might be re-elected. The different societies might either return the same four or others in their place. It was found in Lower Canada on the one hand exceedingly difficult to make any change in the members, and on the other hand any party might by a little underhand work before the election, cause the rejection of candidates. These were the principal reasons which induced the committee to propose the alterations contained in his (Major Campbell's) bill. They thought that each section of the Province should be divided into twelve districts, and that the agricultural societies in each of these districts, at their annual meetings, should elect one of their number to be a member of the Board. This was the principal alteration proposed. It was also sought to separate the Boards of

Arts and Manufactures from the Agricultural Associations, permission being given these two bodies to join together when they saw fit. The Committee thought agriculture was now strong enough to walk alone. In the circular sent round by the Secretary, he mentioned the chief point—the difference in the mode of electing members of the Board. He also spoke of “the dissolution of the Agricultural Association.” That certainly was discussed in the Committee, and it was felt that if the Board of Agriculture was elected in the manner he (Major Campbell) had stated, that they would then fully represent the agricultural population, and that there was no necessity for sending up delegates every year merely to choose the next place at which to hold the Exhibition and to elect the officers of the Society. Major Campbell concluded his remarks by assuring the meeting that the Lower Canada Board did not in the least desire to dictate. He merely appeared to explain the views they held.

Col. Saunders, delegate from South Wellington, said the principal objection felt in his district to the Board of Agriculture was the way in which its members were elected. There was no chance of putting a new member in. The people of Guelph tried it for some time, but were quite unsuccessful. Major Campbell's bill entirely met their views. Each district would then have a chance of sending to the Board a man in whom it trusted. He was sure a great majority of the farmers took this view.

Mr. Jackson, delegate from North York said the Society he represented, felt that some other mode of electing members to the Board was wanted than that now in use. They had felt this for many years. But he was not quite sure Major Campbell's bill met the difficulty. It provided that the members of each district should meet for the purpose of electing a member. Was the end to be gained worthy the labor it would cost? Each district would spread over several counties, so that the members of the Societies would have to travel many miles to the place of meeting. The Society to which he (Mr. Jackson) belonged, thought this would be a difficulty in the way of the effectual working of Major Campbell's bill.

Mr. Johnson, from Middlesex, said he had not met a man in his travels who did not approve of the new method proposed for electing the members of the Board. With reference to what the chairman had said, that the Board of Agriculture would be destroyed by the Bill of last session—

The Chairman had not said so.

Mr. Johnson said the circular that had been issued, at any rate, stated that by the bill of last session the Agricultural Association would be destroyed. He (Mr. Johnson) did not see

it in that light. The members elected by the districts would constitute the Board, and the whole thing would go on regularly enough.

Mr. Barker, of East York, expressed himself in favor of an alteration in the mode of electing members to the Board.

Mr. John Foott, Port Hope, said he thought there were no two opinions as to the desirability of effecting an alteration in the mode of electing the members of the Board. But there was another matter of perhaps greater importance. It was felt that the interests of the agriculturists had been subordinated to those of the artists. The farmers who brought in their cattle to the Provincial Show had to pay \$5 for a shed, while the Mechanics had expensive buildings erected for them and used them free of cost. Let the Board of Agriculture be separated from the Board of Arts, and allowed to unite when they thought it their material interest to do so.

Mr. Thomas Stock, of North Wentworth, was not quite sure that the Board of Agriculture was strong enough to stand alone without the assistance of the Board of Arts. He felt that they could not offer sufficient attractions to the public at the annual exhibition. He agreed with the previous speakers that an alteration in the mode of electing members of the Board was necessary. The objection taken by the delegate from North York was not valid. The farmers took greater interest in the Society than that. Neither twenty miles, nor one hundred miles would stand in the way.

Mr. Archibald Young, of Lambton, moved, —“that the 12th and 13th sections of the Bill before Parliament last session, relating to the mode of electing members of the Board of Agriculture, be approved by this meeting.”

The 12th and 13th sections are as follows:—

“XII. Upper and Lower Canada shall each be divided into twelve agricultural districts designated by number, as in schedules A and B annexed to this act, and each comprising the counties designated.

“The Agricultural Societies in any electoral Division, Parish or township in each District shall, at their annual meetings, nominate and elect one person to be a member of the Board of Agriculture of the same section of the Province; and the person who shall obtain the majority of the votes of the Agricultural Societies in a District, shall represent the District at the Board of Agriculture; and the Secretary of each Society shall, within eight days after such election, forward to the Minister of Agriculture the name of the person chosen by such society.

“XIII. The first election shall take place at the annual meetings in 1862, when six Districts, to be named by the present Board, in each section of the Province, shall each elect a member to replace the four members then

retiring from the said Board respectively. The other six Districts in each section of the Province, shall each elect a member at the annual meetings in 1863, to replace the remaining four members, whose term of service will then expire."

At this stage of the proceedings, it being half-past one, the meeting adjourned an hour for refreshment.

Upon re-assembling,

Mr. James Cowan, M. P. P., seconded by Mr. Ross, moved,—“That the meeting proceed to take into consideration the Agricultural Bill passed by the House of Assembly last session; that the Bill be read clause by clause by the Secretary, and the sense of the delegates taken on each clause.”

Mr. Barker, seconded by Mr. R. L. Denison, moved,—“That the existing Statute, under which we now act, be taken up and considered clause by clause, and that such amendments and alterations as may be deemed necessary be added.”

Mr. Barker's amendment was lost. Mr. Cowan's motion was declared carried.

The Secretary then proceeded to read the Bill of last session, clause by clause.

The first clause is as follows:—

“1. The Bureau of Agriculture and all Agricultural Societies and Boards of Agriculture lawfully organized or established shall continue to exist, except in so far as the said Bureau, or such Societies and Boards, are altered or affected by this Act.”

The first clause in the present law reads as follows:—

“The Bureau of Agriculture and all Agricultural Societies, Associations and Boards of Agriculture, incorporated or otherwise created, continued or recognized by or lawfully organized or established under the repealed Act, passed in the 16th year of Her Majesty's reign, chap. 11, shall continue as if the said Act were still in force, except in so far as the said Bureau, Association or Board are altered by this Act.”

Col. Denison considered if the first clause was passed, the old Agricultural Association would be abolished. He did not think this was right. The old Association had spread its branches and roots far and wide. It had life members all through the country, who would cease to be members of the Agricultural Association; and if that were the case, the Association would be deprived of its agricultural character altogether.

Mr. Sheriff Ruttan said the great point was to satisfy the country that it was fairly represented at the annual meetings.

Hon. G. W. Allan said if the old association were done away with, the doors would be closed to amateur agriculturists—a very important class who had aided the Society.

Hon. D. Christie said the objection taken to

the constitution of the Board was that it was a close corporation. But what was the remedy sought? It was proposed to do away with the old association, and to place the management of the whole affair in the hands of twelve men, over whom there was no check, in fact the new Board would be a closer corporation than the old one. He considered it would be a great calamity to the country when the members of the Board were not compelled, at least to appear once a year, face to face with the delegates.

It was ultimately agreed, after considerable conversation, to add the words, “and associations,” after the words “the Bureau of Agriculture and all Agricultural Societies,” as a means of removing the objections raised.

The clause was then carried.

The several clauses were then read and adopted as far as the eighth.

The ninth clause provided that out of the whole amount voted for the encouragement of Agriculture, four and a half per cent. in Lower Canada, and in Upper Canada two and a half per cent. thereof shall be appropriated and devoted to the promotion of Agricultural Instruction and information.

2. The Board of Agriculture may in its reports to the Government indicate in what manner this sum should be employed.

3. Of the whole amount voted for the encouragement of agriculture, ten per cent. in Upper Canada, and eight per cent. in Lower Canada thereof shall be placed at the disposal and in the hands of the Board of Agriculture for the purpose indicated by law.

Mr. Jackson moved in amendment to this clause the parallel clause in the present Act.

The clause reads as follows:—

“Out of the sums appropriated for agricultural societies in Upper and Lower Canada respectively from Provincial funds, two and one half per cent. shall be applied under the authority of the Governor in Council towards the promotion of agricultural instruction and information.”

Major Campbell pointed out that the clause in the bill had been unanimously agreed to in Lower Canada, and presumed that the meeting did not want to deprive the other section of the Province of the appropriation.

Mr. Solmes moved that the 2½ per cent. for Lower Canada be struck out of the clause. He appreciated the justice of the remark made by Major Campbell.

Mr. Cowan, M. P. P., moved;—“That out of the whole amount voted for the encouragement of agriculture in Upper Canada, 2½ per cent. thereof may be appropriated and devoted to the promotion of agricultural instruction and information by the Board of Agriculture in that section of the Province.”

Mr. Stock seconded the amendment, and pointed out that if the Bill remained as pro-

posed, the deduction of the  $2\frac{1}{2}$  per cent. was compulsory. Under the amendment it was discretionary.

Mr. Sheriff Ruttan contended that by the 2nd section it was discretionary with the Governor in Council to deduct the money. Hitherto it has not been deducted.

Mr. Cowan's amendment was carried.

The second and third sections of the clause were also carried.

For the tenth clause of the Bill, stating what persons shall be *ex-officio* members of the Board of Agriculture, the tenth clause of the present act was substituted; with the President and Vice-Presidents of the Association added as *ex-officio* members of the Board.

The 11th clause was adopted.

Mr. Ostrom moved in amendment to the 1st section of the twelfth clause (quoted above,) that the districts be eight instead of twelve.

Mr. Stock spoke against the amendment. He did not think twelve too large a number.

Dr. Craigie thought that the best way to constitute a Board would be for each county Association to elect a delegate. These delegates should meet and elect an Executive Committee of six or eight members.

Mr. Solmes agreed with Dr. Craigie. The County Society of Prince Edward was strongly in favor of appointing delegates, and he (Mr. Solmes) thought the counties would at least bear half the expenses.

Mr. Sheriff Ruttan moved—"That the present mode of electing the members of the Board of Agriculture is unsatisfactory, and that in future each County Agricultural Society shall at their annual meeting in January, elect one delegate, all of which delegates shall meet at—on the first Tuesday in February, and then and there shall elect eight gentlemen who shall form the Board of Agriculture."

Dr. Craigie seconded the amendment.

Mr. Barker moved in amendment to the amendment, "That the several county societies shall at their annual meeting, name two persons to act as delegates, who shall, at the meeting of the Provincial Association, at its annual Exhibition, have each a voice in the election of members of the Board of Agriculture, and the election of such members shall take place on the evening of Thursday, in the first week of the exhibition."

Mr. Blake seconded this amendment.

Mr. Fisher wanted to know why it was necessary to change the constitution of the Board at all? Had the Board not gained the respect of the farmers of the country? Did gentlemen think they were going to get a better Board? If they did, it was their duty to point out why a change was needed. Let those who were so anxious for a change speak out. Not one single reason had been given for it.

Mr. John Tilt was in want of the same kind

of information as Mr. Fisher. He did not want change for the sake of change. Neither did those whom he represented.

Mr. Jackson said it surprised him a little to hear that change was not needed. Why, then, was this meeting called? At the last meeting of the Association in London very great discontent prevailed at the manner in which the Board was elected. It was found impossible to infuse new blood into it.

Mr. Oliver Blake made an appeal on behalf of the old constitution. What had they done? What were the complaints against them? He had not heard the first word of complaint.

Mr. Cowan suggested that Mr. Sheriff Ruttan should so modify his motion as to cause the delegates to meet at the Annual Exhibition for the election of the Board.

Col. R. L. Denison said Mr. Ruttan's motion was a good motion. But Mr. Barker's motion was better, because there would be a good deal of difficulty in getting the delegates to attend a meeting in the winter. But if—as Mr. Barker proposed, the meeting was held at the time of the Provincial Show, there would be plenty of delegates to attend. He hoped Mr. Sheriff Ruttan would withdraw his motion.

Mr. Sheriff Ruttan had proposed the amendment because he wanted to popularize the Association. He had lately seen a disposition to hold the exhibition in one particular portion of the Province. He was opposed to this centralization. He wished to see the exhibition pushed into every nook and corner of the Province; to be taken east to Kingston, and not confined to the west. He was afraid to name for a day of meeting one of the days of the Provincial Fair. He had seen so much of the difficulty attending the transaction of business on these occasions. Besides if the delegates met at some other time, in a quiet room, much of the "electioneering," and many of the annual quarrels would be avoided.

Mr. Barker's amendment was then put from the chair, and carried by a majority of four—26 yeas to 22 nays.

Mr. Cowan said it was now decided how the members of the Board should be elected. He (Mr. Cowan) moved "that the number of elected members should be eight."

Mr. Solmes seconded the motion.

Mr. Cooley moved, seconded by Mr. Jackson, "That the number of elected members be twelve."

Mr. Cooley's amendment was carried by a vote of 24 to 22.

The meeting then, at six o'clock adjourned for one hour.

Upon re-assembling—The several clauses of the bill were read and approved as far as the 25th.

Hon. Mr. Allan, seconded by Mr. Beadle, moved in amendment to clause 26, the following:

—"Every Horticultural Society in any city, town, or incorporated village, incorporated under this act, or which may have been incorporated under any other act of the Provincial Legislature, shall be entitled to a public grant, equal to the amount subscribed by the members of such society and certified by their Treasurer to have been paid into his hands in the manner provided by the section of the act relating to Agricultural Societies, provided that the whole amount granted to any such society shall not exceed £100 in any year." Carried.

Clauses 27 to 29 were adopted.

In place of clause 30 in the bill, clause 48 of the existing statute was substituted, on motion of Mr. Barker.

The 31st clause was adopted, with the additional proviso, that Township Societies should contribute \$10 to the funds of the County Society, either by membership or otherwise.

Clauses 32 to 36 were adopted.

Clause 37 was adopted, with the following addition, on motion of Mr. Barker, "that in the event of the Secretary or Treasurer dying or resigning office during the term for which he has been elected, it shall be the duty of the Directors and they are hereby empowered to nominate and appoint a fit and proper person to fill the office for the unexpired term of the person so dying or resigning as aforesaid."

Clauses 38 and 39 were adopted.

The 40th clause was adopted with the addition of the same proviso contained in the old act, giving certain County Societies \$1000 per annum.

Clauses 41 and 42 were adopted.

In place of clause 43 in the bill, clause 61 in the act was substituted, upon motion of Colonel Denison.

The clause in the bill was as follows:—"The Board of Agriculture shall receive from Government, and pay over to the county societies, the Public Grants to which they are respectively entitled"

The 61st clause of the present act has, in addition to the above, the words "and the said Board may retain for the use of the Agricultural Association, one-tenth part of all such grants."

Clauses 44, 45, 46, 47 and 48 were approved.

The sections relating to Lower Canada were passed over.

Mr. Cowan said there was a feeling in the section from which he came, that the township shows were too small to do much good, and detracted from the county exhibitions. He therefore moved:—"That the amount paid to any township society from the funds of any county or riding Society, shall not exceed the amount which such township Society would be entitled to receive, were all the townships in such county or riding to organize township societies."

Mr. Rykert seconded the motion.—**Lost.**

The 71st clause was approved.

A number of clauses following related to the Board of Art and Manufactures.

Dr. Beatty said these clauses provided for the separation of the Board of Arts from the Board of Agriculture. This separation was desired in Lower Canada, but not in Upper Canada. Some gentlemen had indeed said that the arts and manufactures were able to walk alone. But how were they to walk alone? Agriculture got a grant in each section of the Province of \$52,000 a year; but arts and manufactures of only \$2,000. Unless the Legislature would bestow a grant on the Boards of Arts and Manufactures, they could not "walk alone" just yet. Dr. Beatty went on to defend the present union, and moved, seconded by Mr. Barker—"That this meeting disapproves of the separation of the Board of Arts and Manufactures and of the Board of Agriculture, so far as relates to the holding of joint exhibitions in Upper Canada as proposed by the bill under discussion." Carried.

Dr. Beatty read a number of clauses relating to the Boards of Arts and Manufactures agreed upon some time previously by the Boards of Arts and Manufactures, and by the Board of Agriculture.

Mr. Beadle seconded by Col. Denison moved that they be approved by the meeting. Carried.

[The clauses were very lengthy. They were published in the April, 1861, number of the *Journal* of the Board of Arts and Manufactures, and having been previously well considered elicited no debate.]

The meeting next proceeded to consider a number of clauses proposed by the Board of Agriculture and the Board of Arts and Manufactures, as an addition to Major Campbell's bill, immediately following his clauses constituting the Boards of Arts and Manufactures. The proposed additions were published in the number of the *Agriculturist* of April 16th, 1861, and are very similar in purport to the clause in the present act relating to the Provincial Agricultural Association. They would have the effect of preserving the Association, which would be abolished by the bill of last session. They were adopted by the meeting without discussion.

On motion of Dr. Beatty, a new clause was adopted to the following effect.

"The Council of the Association shall have power to grant licenses to parties to sell refreshments upon the premises enclosed for the Exhibition."

Mr. Sheldrick moved, seconded by Mr. Solmes, that the Presidents and Secretaries of the Board of Agriculture and the Board of Arts and Manufactures be a committee to draft a bill in accordance with the action of this meeting, and to print a sufficient number to distribute among the various Societies, the members of the Legislature and of this Convention.

Col. Denison moved that the draft be published in the *Journals* of the respective Boards.

Col. Denison's amendment was carried.

Mr. Cooley moved, seconded by Mr. Barker, "That Messrs. Allan, Christie, and Denison be a committee to draft an address of condolence to her Majesty, and that it be signed by the Chairman on behalf of the meeting." Carried.

#### THE WORLD'S FAIR.

Col. Thomson said he begged leave to say a few words upon another subject. He was one of the commission for collecting articles for the great International Exhibition in London this year. Parties desiring to exhibit were requested to send their samples to London, C. W., by the 18th of this month; in Hamilton by the 20th; Toronto by the 22nd; Kingston by the 24th. A general selection would be made at Montreal by the commissioners. The goods had to be in England by 31st March. The share allotted for the exhibition of Canadian products was not so large as in 1851, but it was to be feared so much would not be wanted. The Government had only placed \$6,000 at their disposal this year. In 1851 they placed \$60,000, and for the Paris Exhibition, \$80,000. However, the commission were determined to do the best they could.

A vote of thanks was then given to the Chairman and the Convention adjourned *sine die*.

#### County of Welland Agricultural Society.

We have been furnished with the following abstract of the report of this Society for the past year, for publication in the *Journal*:—

The number of people congregated to witness the Fall Exhibition was greatly in advance of any of its predecessors.

The entries at the Fall Exhibition were not so great as at that of last, being 547 against 684. However, the converse obtained in regard to the Spring Show. The following synopsis in regard to the entries at the Fall and Spring Shows may prove interesting:—No. of stallions entered, 14; of two years old stallions, 2; of team horses, 6 pairs; of pleasure horses, 4 pairs; of three years old colts, 4; of two years old colts 11; of 1 year old colts, 11; of buggy horses, 18; of saddle horses, 15; of mares and colts, 15; of bulls over two years, 4; under two years, 1. Thorough-bred stock,—of cows, 5; of two years old heifers, 3; of one year old heifers, 5; of calves, 5; of grade stock—of oxen, 4 yoke; of three years old steers, 4 pairs; of two years old steers, 4 pairs; of one year old steers, 1 pair; of cows, 9; of two years old heifers, 6; of one year old heifers, 6; of calves, 4.

The display of sheep was excellent, and exceedingly creditable to their owners, both in

regard to the number and quality of animals exhibited.

The grain department was inferior to that of last year, arising no doubt from the lateness of the spring, and the wetness of the latter part of summer; rust in many cases supervening, and causing a deficiency in the quality of the grain thus attacked.

But there was still a greater deficiency in the root and fruit departments, particularly in the latter, and this may have arisen from two causes; 1st. from the over-loading of the previous year, and 2nd. from the late frosts in the spring. Not a solitary peach was shown.

The manufacturing department compared favourably with those of former years. There was an excellent combined mower and reaper shown, which elicited much commendation from those versed in such implements, said implements being manufactured by Messrs. McDougal & Russell, Fort Erie.

The Ladies, as usual, did their duty in regard to the filling up of their department, and many of the articles exhibited by them shewed correctness of design and elegance of finish.

The directors further state that they appropriated the sum of \$50, of which sum only \$40 28 was expended, for the erection of a temporary building, to hold the products exhibited at the last show; the materials of said erection being available towards the construction of a more permanent building at some future time.

In conclusion, the directors express their gratitude for the support bestowed on their labours by a generous public, and hope that the same may be extended even in a greater degree to their successors in office.

A. R. SCHOLFIELD, *President*.

#### East Durham Agricultural Society.

This spirited Society held their Annual Meeting at the Town Hall, Port Hope, on the 16th ult., and concluded the proceedings of the day by partaking together of an excellent dinner, at which we are informed no intoxicating liquor was used, at Church's Hotel. The particular occasion of this friendly re-union was the presentation of an address, on the occasion of his retiring from office, to W. F. Allen, Esq., late President, and formerly Secretary of the Society, and who, we know, has been a most energetic and useful officer. Amongst the other invited guests were the Rev. Mr. Hunt, the Rev. Dr. Shortt, Messrs. John Wade, R. Hume, and A. Alcorn. After due justice had been done to the viands upon the table, the farewell address was presented, which, with the reply, we subjoin:

*To W. F. Allen, Esq., retiring President of the East Durham Agricultural Society.*

DEAR SIR,—It is with very great regret that the members of the East Durham Agricultural

Association have been made aware of your intention to leave the County, and that your business affairs require you to reside outside the limits of our Association, of which you have been, for the last seven years, a worthy and useful member.

We are proud to be able to say, that you commenced your career as an Agriculturist in connection with this Association, and that you have been treading in the footsteps of your father, who was for many years an eminently useful member of this community.

Agriculture is a noble employment. Men of all grades—some of them much distinguished for learning and refinement—after having employed their youth and early manhood in other pursuits, have devoted their declining years to Agriculture, believing it to be, of all occupations, the one best calculated to promote peace and domestic happiness.

It is pleasing to see young men of talent and education devoting themselves to this noble work. We hope that you will still be found in the ranks of the Agriculturist; and that your future life will be spent in carrying out those principles which you have advocated in the past.

We cannot allow you to retire from amongst us without offering you some mark of our esteem and regard.

Please accept this Address, as a token of respect from the Directors and members of East Durham Agricultural Association.

Signed on behalf of the Association,

A. CHOATE, *President.*

Port Hope, January 16th, 1862.

#### MR. ALLEN'S REPLY.

I thank you for this generous expression of your esteem. I also thank you, Mr. President, for the kind manner in which you have alluded to the usefulness of my father as an Agriculturist. I am proud of being an Agriculturist, and, it gives me much pleasure to look back on my past connexion with the East Durham Agricultural Society, and I only regret that I have not brought greater ability to the furtherance of its interests. My energies thus far have been devoted to the interests of Agriculture; and although I have had flattering inducements held out to me to forsake this pursuit, still, I am determined to continue a farmer, believing it to be, as you express it, "the most noble employment we can engage in."

Please accept my warmest thanks for your kind wishes for my future prosperity and happiness, and I beg to remain, Your obedient servant,

W. F. ALLEN,

To the President, Directors, and Members of  
E. D. Agricultural Society.

#### Drainage.

We take from the London *Prototype* the following account of the trial of a new draining

plough invented by Mr. R. Robson of London Township, which, if it accomplishes all that is stated of it, may turn out a valuable implement:—

MR. ROBERT ROBSON'S DRAINING PLOUGH.—We were much gratified with the result of a visit paid the farm of Mr. Robert Robson, of London Township, on Monday, in company with Mr. John Carling, our city member. Having heard so much said of the properties of the draining plough, the effort of the inventive genius of Mr. Robson, we resolved to personally inspect the invention, and, certainly, at first sight, a person would naturally be led to smile at the novel appearance of this useful implement, made up as it is in the most simple, unpretending, and in fact, entirely primitive build; but when placed behind two horses, and a careful ploughman, disappoints the veriest sceptic in agricultural matters, and cuts a drain, which, for width and depth, is truly marvellous, doing away with a large amount of manual labour, and consequently, expense. Every one acquainted with the nature of thorough draining will know the utility of the system when successfully and perseveringly carried out. Smith, of Deanton, Scotland, the world renowned thorough-drafter, has given the farming community a criterion to judge by, in years past, of the wonderful success, as well as the advantages that attend a perfect system of thorough draining, and to him, we think in those modern times, is due to a large extent, the commendation for pushing this beneficial system of land culture to the right point of prosperity—and we all know he has reaped a rich reward, both as regards the benefits he has conferred upon the agricultural world, besides his own pecuniary advantages, which were handsome, and largely remunerative.

In Ireland, in 1843, we witnessed the excellent results and large profits which a large agriculturist reaped, after having for some years carefully copied Mr. Smith's mode of draining, coupled with subsoil ploughing; and now, in our neighboring London Township, we believe the same system may be adopted, and successfully carried out, with half the expense, time and labor, which had to be resorted to in the mode of draining we have alluded to, if farmers will only give Robson's principle of thorough draining a fair and honourable trial. And on Monday last, on our arrival at Mr. Robson's farm, we were not surprised to see a number of intelligent and respectable gentlemen, farmers of course, who had come to test the merits of the new farming implement, and give the people the result of their investigation. This, we believe, was done most impartially, and with a desire to give the tillers of the soil and the inventor himself the advantage, if there were really any advantages in it, of placing in the hands of the farmers a plough for draining purposes, calculated to lighten labor and save men's toil, and throw more of the burden of it upon horses, while, as we have remarked, considerable economy is practised at the same

time. The plough, which we observed for the first time upon the exhibition grounds, and, indeed, in concert with many others, smiled at, is, we repeat, a novelty in appearance, seems to be of the mediæval ages, and one would be more likely, when getting a first look of it to take up one of Wilkie's best axes, and "hack it down," with a fell sweep to the ground. Suffice it to say that it is formed of the roughest material, a simple piece of wood constructed in all points as a plough, *with two sides or mould boards*, which open up a drain three feet in width at the top, and thirty-two inches deep. A narrow spade, (much like that used for cutting turf,) is then taken, with which the bottom of the drain is cut eight inches deep, and tapering on each side, about an inch and a-half at the bottom, and four and a-half inches wide at the top. Before this operation is commenced, we should remark that an ordinary plough precedes the draining plough, by running a furrow on each side, so as to prepare the ground for its reception. After the drain has been cut, a sod is cut with the operating plough, of four inches wide at the top, with one of its surfaces grassy; this is taken and placed by a man on the top of the water-course which has been made with the narrow spade, taking care to have the grassy side of the sod down, and when placed on the drain resembles much the slanting or oblique thrust of a bridge, or the key-stone of an arch, evidently locking the drain effectually, and although simple in appearance, apparently possessed of great durability, for Mr. Robson, after finishing the laying of the soil, placed one of the horses on the drain, made him walk over it, without the least detriment having been done. In cases where the land is sandy, or quicksand, the inventor of the draining plough places a number of faggots, jointed together, in the drain, with straw underneath and above, which he states, works remarkably well, and proves that the difficulties incident to land subject to slide, may be effectually done away with, and a good substantial water-course secured for the carriage of the water.—The draining plough has been proved by calculation, able to do as much work per day as twenty-five men, with spades and shovels. Mr. Robson ploughed with his drainer two hundred and twenty-five feet, while five men dug during the same time, about fifteen yards, or fifty feet, the plough, it was remarked, doing the labor in a much superior manner than that accomplished by the men.

In the matter of screened-gravel drains, we may here state that the gravel is equally suitable for sewerage, and by computation Mr. Robson has ascertained that one bushel of gravel will make fourteen feet of drain. As regards the probable cost of the drains, Mr. R. says that two men and a span of horses, (the latter working only two hours a day) can complete forty rods of draining in a day, and at this calculation, it would not cost more than two dollars for forty rods or five cents per rod, the

lowest charge for making drains we have heard of in this fast age, and allowing all who are anxious to have well-drained farms the chance of making them at a price that "bangs Banagher." We strongly advise those who are in love with Mr. A. P. McDonald's theory of thorough draining to call on Mr. Robson, and after a trial of his scientific invention, which has been tested in various ways, they will have no reason in the future to cry out, "My land is too wet; I can't grow anything in it."

After the process of formation and closing of the drain was over, the gentlemen present adjourned to the hospitable home of Mr. Robson, where his health was proposed in a very flattering manner by Mr. Carling, with several well-timed remarks upon the success of his farming invention. It was then moved by Lionel E. Shipley, Esq., seconded by Wm. Balkwill, Esq., and

*Resolved*,—"That we, the undersigned, having been witnesses of the successful working of the thorough-draining plough, the invention of Mr. Robert Robson, of London Township, deem it a most useful auxiliary in farming operations, and cheerfully recommend it to the farmers of the County of Middlesex, and to the people of Canada generally, as a useful and suitable implement in agricultural pursuits, combining cheapness, economy and usefulness in the draining of land."—Carried.

tie, Andrew Robson, Robert Williams, Lionel  
W. Shipley, Robert Waugh, John Lamb, John  
Bowman, Ogle Blair, John Calvert, Oliver  
Wilson, Hugh Kennedy, James Blair, John  
Eleback, Philip Rosser.

GEO. ROBSON, *Chairman*.

### Judging of Cattle.

At the last meeting of the Smithville Fat Cattle Show, Mr. Torr made in his speech one capital point:—"This was in denouncing the absurdity to which the use of the tape is now carried; and we quite agree with the speaker when he said that it not unfrequently tends more to destroy the correctness of a man's eye for form and general contour than of any absolute good. And yet how frequently do we find men, who should know better, rushing up to an animal that they barely look over, save for the purpose of throwing the measure round him? We were never inclined to believe much in a Judge whose best arguments for what he did were a knotted string and a pencil; and we hope the long-called-for rebuke from so able a Judge as Mr. Torr is himself, will teach others to rely more upon all the eye and hand can tell them as to form and character. Of course in some cases it might be as well to be armed with such precise information, like the carpenter under cross-examination, who, in answer to the

qu w far he was from the prisoner when the assault occurred, replied in a moment, 'Seven feet eight inches and three-quarters. I thought some fool or other might be asking the question, so I took out my two-foot rule and measured it.'"

**MINKS AS INSECT-CATCHERS.**—A correspondent of the Rural New-Yorker, who seems to make a business of raising minks for their fur, relates the following in regard to their catching grasshoppers and bee-moths:—"Two years ago last May, I caught seven young minks. I made a pen of boards near my bees, twelve feet square, and put them in it. About the first of July grass-hoppers would occasionally sail in, and they would jump and catch them very quick. It soon became sport for boys to catch grass-hoppers and throw them on the side of the pen, to see the minks jump and catch them. Hearing the same jumping at night, I went out to see what was going on, and I found they were catching millers. The millers were so thick about my bees that I could catch about thirty or forty a night in a pan of buttermilk, and now I have no nullers about my bees. My minks cannot climb a rough board fence four feet high. They have young once a year,—from five to eleven,—and before I take off their pelts I keep them in the dark for about one month, to make them darker than the wild ones."

## Horticultural.

### The New French Roses.

Scores of new roses are sent out by the French every year. Some of them, perhaps one in a dozen, prove valuable, and in a few years become popular, and their names are as familiar as "household-words"—like *Giant of Battles*, *La Reine*, *Caroline de Sansal*, &c.—but the remainder are forgotten in a few years. A correspondent of the London *Florist*, who has made a sojourn among the rose-growers of the continent, names about sixty new varieties that are to be sent out this winter and next spring as candidates for public favor. He says:

"I thought that the best service I could render during my recent visit to France was to obtain such information upon the subject of the forthcoming roses as might gratify my own curiosity, and be somewhat of a guide to them. I have made the best use of my eyes and ears that I could; have visited Margottin, Verdier, Marest, Touvais, Troulliard, Portemer, &c.; have obtained lists of the new varieties, and, in fact, done my best to get together some information on the point, and the conclusion that I have come to is, that we are not to expect any very striking additions to our lists this season. There are some which promise well, but when I say that there are, I verily believe, nearly a hun-

dred new ones to come out, it will be seen how difficult is the task of selection, especially as one feels that under the most favorable circumstances not one-tenth of these will be retained in our lists; in such a case, one must rely more on the known characters of the venders than on anything else. Men like Margottin and Marest will not willfully deceive; they may be mistaken, but they regret it as much as the public when it is so. There was one matter in the cultivation of roses, which I heard from Troulliard, of Angers, which struck me forcibly as one likely to be of service to us, and this is to graft low on stocks of the Dog Rose, raised from seeds. However excellent the Manetti may be for strong, vigorous growing kinds, I think that no one can say that it is equally good, especially on strong soils, for the more delicate constitutioned kinds; for they, not having the power to receive the sap, are soon overpowered, the stock begins to throw up suckers, and the rose languishes and dies; while stocks of the Dog Rose taken from the hedges, are, on the other hand, generally so defective in root, that they answer badly for that purpose, but by sowing seed of the Dog Rose you obtain nice healthy stocks, with abundance of fibrous roots, not too vigorous in character, and giving a fine, healthy start to the rose; and is also more permanent than it is likely to be on the Manetti; it is, at any rate, worthy of the consideration of rose growers, and I am not aware that it has yet been tried in England."

### Botanical Society of Kingston.

We observe that this valuable society has lately held its annual meeting for the election of officers. The following gentlemen were appointed for the ensuing year:—

PRESIDENT.—Principal Leitch, D.D.

VICE-PRESIDENTS.—Prof. Williamson, LL.D.; Prof. Dickson, M.D.

#### COUNCIL.

Prof. Fowler, M.D.; W. G. Hinds, Esq.; Prof. Litchfield, M.D.; M. Flanagan, Esq.; Prof. Horatio Yates, M.D.; Wm. Ferguson, Esq.; J. Duff, Esq.; J. J. Burrows, Esq.; Geo. Baxter, Esq.; Octavius Yates, M. D.; Thos. Briggs, Jr., Esq.; Professor Lavell, M.D.; Augustus Thibodo, Esq.; Rev. Prof. Weir, A.M.; John Watkins, Esq.; John Creighton, Esq.; Rev. Prof. Mowat; Arch. J. McDonell, Esq., Recorder; J. Carruthers, Esq.; Hugh Fraser, Esq.; Jeremiah Meagher, Esq.; Hon. Alex. Campbell, M. L. C.

SECRETARY.—Prof. Lawson.

TREASURER.—Andrew Drummond, Esq.

#### CURATORS.

Mr. J. F. Ingersoll, Mr. John K. McMorine, Mr. Wm. B. Ferguson, Mr. John Bell, Mr. A. T. Drummond, Jr., B. A.

LIBRARIAN.—Mr. R. V. Rogers, B.A.

## The Dairy.

### Butter Making.

[The following statement is copied from the last number of the *Journal of the New York Agricultural Society*, and will throw some light on the mode of preparing the superior butter found in the Philadelphia Market]. EDS.

PHILADELPHIA, 10th mo., 21st, 1861.

*The process.*—After the milk is drawn from the cows it should be strained into pans properly arranged on a bench for the purpose, with a small quantity of fresh sour milk in each one, to hasten the raising of the cream, which should on all occasions be taken off from thirty to thirty-six hours after being milked, it being found that, standing longer in a large dairy, more is lost by deteriorating the quality of the butter than is gained in quantity. When the cream is skimmed off of the milk into a large cream pot it should be put in the butter hole in the spring, and let stand one day, and then skimmed off, so as to remove any sour milk that may have settled from it to the bottom of the pot, and should be subsequently stirred every day until churned, to prevent rancidity from taking place on the top of the cream by too long standing, which is the main cause of all the strong butter that is made. The cream should be churned twice in the week during the summer months, and all the year where there is a sufficient quantity to warrant it. The temperature of the cream and churn should be about sixty-two degrees, so as to warrant the butter to come right, and in the proper length of time, which should be about thirty minutes. There is as much danger in having the butter come soft by over-churning as by the atmosphere being too hot. In order to regulate the temperature of the cream in the fall, winter and spring, it should be set in a tub of hot water until it comes to the temperature above designated—the butter broken in the churn to the size of peas and chesnuts. The buttermilk should be drawn off through a fine hair sieve from the vent of the churn, which should be about an inch hole. A sufficient quantity of spring water should then be put in, and a few revolutions of the churn, when it should be drawn off, and then another quantity of spring water put in and tumbled in the churn until gathered into a mass. The water should all then be drawn off and the butter cut into cracks, as it lays in the churn, to receive the salt, which should be a pint for fifty pounds, regulating below that, or above that, according to the quantity churned. The butter should then be tumbled in the churn until the salt is mixed with it, and it will then do to take out in ten or fifteen pounds, and lump into pounds, ready for sponging, which should be done by having a sponge of proper

size enclosed in a linen cloth and passed over the lump, by pressure, to absorb the brine and moisture it contains, which should then be weighed and printed if intended for the market. The sponge should be frequently squeezed out of cold water as dry as possible during the sponging and weighing of fifty or one hundred pounds.

*Remarks.*—The buttermaker will see the advantage of this mode of salting and working butter over any other mode, and particularly of the lever or worker, as it is called, from the fact that less of it is exposed to a warm atmosphere at a time, as it must necessarily be where fifty or one hundred pounds are operated upon on a broad surface, making the butter soft and oily, which is detrimental to its quality, however carefully attended to, from the time the milk is taken from the cows. The above plan was perfected by experiment by me, and carried out for a succession of years, as thou knowest, with a success as to quality and sale of my butter not surpassed by any one at the time I was operating. Respectfully, &c.

H. EUCHUS.

## The Poultry Yard.

### Spanish Fowls.

EDITORS OF THE CANADIAN AGRICULTURIST, —Gentlemen,—You copy in your last number under the head of "Profitable Poultry Keeping," a comparative estimate of several breeds of fowls from the *Journal of Horticulture*.—As the notice of one of these breeds is quite contrary to my experience, (I should rather say my wife's, as she is the chief lover and manager of the poultry,) I would guard your readers by being misled by such a statement.

I cannot pretend to give an opinion on the comparative profit of the different favourite breeds. We at first were contented with the common mixed kinds, which, with good management, answer very well, and are perhaps the hardiest. We tried the Cochins and did not like them, they are voracious eaters, which in a suburban abode, where food must be bought, is of consequence. They are always wanting to sit, are awkward nurses, and their flesh is coarse and inferior.

At length we obtained a fine and seemingly pure Spanish cock and hen. We continue to keep and admire them and their descendants, and from actual trial we say: good layers, steady sitters, kind nurses, eggs remarkably fine, flesh very good. We think the Spanish poultry somewhat more delicate than the common sort, requiring a comfortable house, and a little care; possibly the brood may be more difficult to rear than in some other varieties. I do not want to magnify their merits to the

discouragement of others, but having never had finer or more abundant eggs, and that even at the season when they are scarcest, I do not like to see them unjustly condemned, and should feel obliged by your allowing me to say what I have found them as a note on the article I have referred to.

## H.

[Thanks to our correspondent for his interesting communication. We shall be obliged to any of our readers who may favour us with their views and experience on these matters. Eds.]

## Poultry.

*Concluded from Page 53.*

A very important essential in poultry keeping is a proper house. It is not at all necessary to be an expensive or fancy affair, but it must be comfortable, warm, and well ventilated. Heat is sometimes introduced by means of hot air pipes connected with some adjoining furnace; and small stoves are also used for heating. Earthen floors are preferred by many good managers to bricks, boards, or stones, and a quantity of fine sand should be laid down in a corner of the house, or under an adjoining shed, as this helps to preserve the poultry from insects, in consequence of their rolling in it, and using it as a sand-bath. The floor should also be thickly coated over with fine sand, when such can be procured, especially if it is formed of bricks, boards, or stones. The roosting perches are constructed in the form of a wide ladder, the frame in which they are inserted being set in a sloping position against the wall. The perches are placed at a foot apart, and are from one and a half to two inches in diameter. "The value of low perching cannot but be known to most keepers of fine, large fowl, who are sure to break their breast-bone when coming down from high perching, and from which they scarcely ever recover." (Nolan). Boxes or baskets, set near the ground, and furnished with cut straw, must be provided as nests for laying and hatching, and the hatching nests should be placed, if possible, in a quiet place, apart from the other hens. Plenty of pure water is indispensable in a poultry-yard; the inside of the houses, perches, &c., ought to be whitewashed at least twice a year, and kept clean at all times.

Ducks.—The white Aylesbury is a large, fine, and valuable breed, of which the pale bill is a distinguishing point. The Rouen "res mbe wild ducks in colour of plumage and bills. The larger they are the better"—and great size is a characteristic of it—"but no weight can compensate for faulty plumage, or green or leaden coloured bills in the ducks." The Rouen duck is an excellent layer. There are other breeds, but these are the most useful for ordinary purposes.

Duck eggs are generally set under a hen, but the duck herself makes a good mother. The time of incubation is thirty days; being nine days longer than in the case of the hen's eggs. The ducklings should be kept from water for nine or ten days after being hatched, and their food should consist chiefly of soft, but at the same time nutritive matters; such as barley meal and water or milk, mixed thin, being very suitable food. Chopped egg—boiled hard for the purpose—with oatmeal, may also be given moderately. Ducks require little assistance in the way of feeding, if they are allowed to ramble through the fields, where they are of much service in picking up slugs and other insects; but if they are confined they must be regularly and well fed on such food as we have mentioned in the case of fowls, and when fattening for table use, it is recommended to mix treacle and chopped mutton fat with the barley meal, &c., upon which they are fed.

THE GOOSE.—The common domestic goose is either of a white or gray color, the large white sort, called the Embden goose, being very superior. Still, the geese which are kept by the majority of ordinary farmers in the country want size—a very serious defect, for size is everything in geese; and, therefore the best breed to cross with is the Toulouse, which possess great size, as well as other desirable qualities. "Their prevailing colour is a blue gray, marked with brown bars; the head, neck (as far as the beginning of the breast), and the back of the neck, as far as the shoulders, of a dark brown; the breast is slaty blue; the belly is white, as also under the surface of the tail; the bill is orange-red, and the feet are flesh-coloured." (Nolan.)

Geese are long-lived birds, and they do not reach their best as breeding stock until they are three or four years old. One gander is allowed to four or five geese, and if well fed, laying will commence by the middle or end of January. Eleven eggs are a sufficient number to set under a goose, and the period of incubation is thirty days. Goose eggs are occasionally hatched under turkey hens, and common hens are also used for this purpose, but the latter will not cover more than four goose eggs. The sitting goose must be regularly supplied with food, and the first food of the goslings may consist of bread soaked in milk, bran mixed with boiled potatoes, and some boiled vegetables,—cabbage, greens, &c.—mixed with the food are very useful. The food must not be cold, but, at the same time, not too warm. If the weather is good, the goslings with their mother, may be turned out on a grass field, when the former are ten days or a fortnight old; but if the weather is cold or wet, they should be confined to a shed, and carefully fed. A good run at grass is of great service—in fact, indispensable for young geese; and therefore, we generally find that numbers of them are reared near commons, or similar tracts of ground; but when intended for an early market,

they must be well fed in addition to what they pick up. Boiled potatoes, or turnips, mixed with bran, barley meal, or oatmeal, and given in a slightly warm state, will hasten the fattening process. Boiled rice is also excellent food, and with moderate attention the young geese may be made quite ready for use by the time they are three months old. Generally, however, they are kept over until the crops are reaped and carried, when a run on the stubble puts them in good condition, which may be still further increased by a subsequent confinement in a house for a fortnight or three weeks, during which time they are liberally fed on oatmeal, peas, beans, barley, or Indian corn meal, all mixed up, with boiled potatoes or swedes. They must be supplied with water, gravel, and plenty of clean, dry straw.

**THE TURKEY.**—This class of poultry is one of the most valuable, and, from the want of success which sometimes attends the rearing of them, they are often considered the most troublesome. The Cambridge breed is larger than any other, is of a white and black color, sometimes gray, and occasionally mixed with copper coloured tints. The American turkey has a bright, metallic hue, and has more of the wild nature than any other variety.

Thirteen eggs are a sufficient number to set under a turkey hen, the period of incubation being from twenty-eight to thirty-one days. During incubation the hen must be as little meddled with as possible, beyond what is necessary in giving her food and drink. When the chickens are hatched, leave them alone without handling, do not offer them food of any kind for ten or twelve hours, at least. "If you are foolish enough to cram pepper-corns down their throats to warm them; or to dip them, either head over heels, or the legs only, into cold water; to make them hardy; or to give them ale or wine to strengthen them; or to comply with any other of the old wives' senseless traditions, which really seem as if they were intended to *prevent* the rearing of turkeys—you must take the consequences. Many will die—some may survive; of these you may boast as specimens of successful nursing. But does the wild turkey, or any other bird in a state of nature, commit these perposterous outrages upon her infant brood?"—(Art poultry, *Morton's Cyclopaedia*)

The first food should be hard boiled egg, chopped fine, mixed with chopped lettuce, the green of spring onions, or chives. "Green food in abundance turkey-chicks *must* have, intermixed with their more nutritious diet." Moderately boiled rice and oatmeal, or barley meal, made into dough, may also be given to them. "If you have a very old, rich, rotten dung-heap, or spent hotbed, full of little worms, wood-lice, grubs, &c., let the chicks have three or four shovelfuls of that also in the course of the day. But whatever you give them, it is of no use setting it down and leaving them to feed them-

selves; you must stay *and see them eat it*, and watch that each chick takes its share. For if, by any chance, they have been neglected for an hour or two, and have fasted too long, they will then sulk, and perhaps refuse to eat at all. In this case they must be gently crammed, or they will surely not be reared; but it is a most blameable fault in the poultry-keeper ever to let his or her charge fall into this low, mopish state. The great secret in rearing turkeys is to be *constantly* tempting them with a variety of food; every half hour is not at all too often. They *will do* with somewhat less attention; but this untiring officiousness towards them quite pays; their little stomachs should always be full; their growth is most rapid, and, indeed, enormous, if we compare the proportions of a new hatched chick and a bird at Christmas fit for the spit, and weighing perhaps 15 to 16 pounds. Their growth must be unceasingly *sustained* as well as liberally supported; for if it be not, it is not the mere difference between fine and undersized birds, which the lazy and niggardly breeder will have to suffer from, but not half the brood, perhaps not one of them, will ever be reared in the 'shift-for-yourself' system. . . . As the chicks advance in growth, their feeding need not be quite so frequent, but it must be equally profuse; let them have plenty of green food, as well as of corn, wetted barley meal, boiled rice, and insects. A well-hearted lettuce, taken in one hand and shred to them with a knife in the other, is excellent; she next time you go to look at them set a bunch of the thinnings of the onion-bed served out to them in the same way. Never appear before them without some present that they are likely to accept. So you will best make sure of attaining your object—a handsome flock in November. . . . The critical times with turkeys is when they are about the size of partridges, or before; their heads, which had hitherto been clothed with down alone, now began gradually to be covered with fleshy tubercles; the larger feathers, those of the tail especially, are making rapid growth, which is a trying drain upon the strength of the bird. You may, if you please, give them carraway seeds, rice; or other simple tonics; but the only efficient medicine is *generous diet, and plenty of it*, and that by itself will be quite sufficient."

## Miscellaneous.

### The Cerealia,—A Standing Miracle.

In treating of the Cerealia, or corn-plants, as special witnesses for God in relation to man, we pass by the fact, albeit important, that by nature man has no knowledge of his proper food—no instincts even to guide him in the choice of it; and that, had he been left originally to his own resources in respect of it, as the lower ani-

imals are, he would without doubt have perished of hunger or of poison, from eating at random of some deadly thing, or through sheer ignorance of wherewithal to fill his belly. And we pass by also a vast number of other relative facts (their name is legion),—such as the use of *fire* in the preparation of man's food, including the whole art of cookery (simple or complex) as forming a part of the "conditions of his existence;" to say nothing of the necessary connexion that subsists between man's sustentation and man's own head and hands, or between it and his domestic and social relations; all which, bearing directly on the matter now in hand, serve to show that, in respect of that which cometh upon him daily—the care of his fleshly tenement—nature, on the one hand, has in a great measure left him out of her reckoning, while, on the other, God has in an especial manner been "mindful of," and has "visited" him.

All that we purpose doing is, to direct attention to the cerealia as a class of vegetable productions, which, as neither *natural* plants themselves, nor growing *naturally* in any part of the world, demonstrate by facts within themselves—facts which our modern science has ascertained, or has verified, and which may be seen and read of all men, that they must of *necessity* have been produced *miraculously*; and which furnish, moreover, with no tradition as to this, nor any specific reference to them in this relation by Moses, a proof the most striking that can well be imagined, and all the stronger that it is *indirect*, of a special exercise of the Creator's care for His creature man.

The cerealia, which comprises wheat, rye, barley, oats, maize, rice and millet, are beyond all doubt man's proper food—the food proper for civilized man—the possession and the use of which leave him free to devote his energies to the advancement of his being, the multiplication of his race, and the accomplishment of the main object of his existence in the world. Without corn, living on wild roots, or by hunting or fishing, and precariously, or from hand to mouth man is everywhere a savage and a cannibal—improvident, bestial, incapable of taking a single step towards a higher or a better condition. Animal food, indeed, civilized man eats, and was intended, doubtless, to eat; but not his brother's flesh. Such as it is,—beef, mutton, and the like—it comes to him remotely of a plentitude in corn; of the leisure for thought which this affords him; of the habits which tillage engenders; and in many ways besides. Yet corn is his staple food.

Comprised in the great natural family of *grasses*, the cerealia themselves are—all of them—*unnatural* species of this family! Their natural state, because their constant or persistent state—that in which alone they can be cultivated or will grow (unless they be *abused* by man),—and in which alone they are of any value

to him, is one which the botanist designates *abnormal*; the gardener, *monstrous*. And around this central fact in thier history, there clusters a number of other singular facts, all of which, more or less, cause them to stand out apart from every other kind of plant, invest them with a character altogether special, and, when fairly looked at, are seen to be plain and unmistakable "*marks of God*."

2. Let it be noted, first all, as to this condition of *monstrosity*, that, as of holding of other kinds of plants, it is one which is *occasional* only, or *accidental* and *transient*, which can be kept up only by careful cultivation, and which continually tends, notwithstanding, to revert back to the natural and primitive condition. With the cereals on the contrary, this abnormal condition is manifestly *their* primitive or natural, and it is, moreover, their *abiding* state. They have no tendency to degenerate, or to assume a lower, and, relatively to other plants, a more natural grade.

2. Man, indeed may *degrade* them. By a treatment of them of his own devising, steadily persevered in, but attended with some trouble to himself, because requiring several years for the accomplishment of the end aimed at, he can reduce them to the condition of a perfectly natural yet absolutely worthless grass. To understand how this may be done, one or two things must be premised. *Annuals* naturally, bearing seed of such a kind (so monstrous and so large, and withal in such abundance) as draws towards it, or the ripening, all the available energies of the plant, they form no buds at the root (they have in fact, no surplus vigor during the ripening to form any) whence new plants might spring up the following year. Therefore, their seed duly ripened they die, or rather are cut down in autumn, and then they *die out*, root and branch. They are *annuals of necessity*. They die of the exhaustion of seeding. They may be said, to apply an allusion of DeCandolle's, to perish in *child bed*. The natural grasses, however, that are *perennial*—the common grass of the field—bear both seeds and buds, and they bring *both* to maturity. Doing this they spring up year by year spontaneously from the buds they form; and they thus *multiply* as well as thus *perpetuate* themselves, covering the ground as with a carpet, and spreading over it a table of plenty for the cattle that feed on it, and that tread and repose upon it; and for whom, as they can neither sow nor reap nor gather into barns, nor make themselves a bed to lie down on and sleep, the Creator thus provides.

Differing thus widely from the natural grasses their congeners—differing from them, as we have seen, at this that they bear seed of such a sort as demands for the ripening of it, and exhausts, all their inherent vigour, and makes them *annuals*—the cerealia may nevertheless, by man's ingenuity, be converted in *perennials*. It is done by

debaring them from opening their seed. Cutting off the ear, the corn-plant comes in flower, and so hindering it from seeding, the plant, thus treated, will form a bud at its root, and from this bud it will spring up again the following year. If now left to itself, this second year, it will flower and bear fruit. Yet, let it be carefully observed, neither will the fruit have the quality, nor the plant itself the character, which are natural to them. Both the plant and its seed will to a certain extent, have been degraded by the process.

But if again, this second time, the plant is prevented from seeding, by being again denuded of its flower, it will as before, put forth a bud at its root, and spring up the third year. And if year by year this process be repeated, then in the course of ten or twelve years (so it has been found by experiment), the plant will be reduced, bit by bit it will have been degraded, to the condition of a naturally perennial grass, bearing a seed which is good for nothing.

3. Thus degraded by the cunning craft of man, then another fact demands attention, namely, this, that by no care or skill of husbandry can man restore the plant to its pristine state. He cannot bring it back to the condition in which he found it—the state in which God made it and gave it to man. It will remain what man has made it, a wild and worthless grass, perennial indeed intrinsically, yet, vital, destined ere long, having no pith or stamina, “no root in itself,” to give way and disappear before the true and natural grass. A thing of man, it shall not be allowed an abiding place in the world, to breed confusion in God’s own creation. Widely different in man’s power over other plants, wild or cultivated, cultivated by himself. He may raise them above their wild state; it is the business of the gardener to do so; and so doing, and making them abnormal, he may render them highly useful to himself as food. But this done, he must keep them in that state by his own care, intermitting which they will lapse back into their wild state; or thus cultivated, made abnormal by himself, he may at his pleasure let them become wild, and then bring them up again to their cultivated state. Man, however cannot thus play fast and loose with the cerealia. A strange law it is, surely, that to which alone of all plants, the Creator has subjected His own specially artificial plant, the cerealia. Strange that with them man may not intermeddle as he will! “*Nemo me impune lacessit*,” is true of them in a divine sense. Man may not degrade them but at his peril, the forfeiture beyond regain of his staff of life.

4. Unknown, then, not growing anywhere as wild plants, are as mere grasses, which the botanist may point to, and which he may describe, as the types and as the native habitats of the cultivated cereals, there is yet this further to be noted of them, namely, that they grow nowhere

spontaneously or of their own accord. They do not sow themselves, and so spread themselves by their seed over the earth, and to man’s vexation the thistle does, and as do other annuals. Left to themselves, they die out, disappear, and become extinct. Of this, tall and strong of stem and vigorous though they be, one cause is, that perennial plants of all sorts, weeds, thistles, the common grasses, “external agents which they are too weak to resist,” choke and supplant them.

5. The final cause, however, or the reason of the peculiarity now adverted to, as attaching to the cerealia, is to be found in the one appointed condition of their growth, a condition peculiar to them. “*In the sweat of thy face shalt thou eat bread*,” we have the divine expression of this condition, if, indeed in this other, “*Thorns and thistles shall ground bring forth to thee*,” we have not also the divine explanation of the fact that they will not grow spontaneously. Made expressly for man, given directly into his hands by God, man has himself been put in trust, for his own behoof, of their life and growth. “Behold, I have given you every herb bearing seed (seeding seed) which is upon the face of all the earth; to you it shall be meat,”—a kind widely different, so far, from the “green herb” which He gave for meat to every beast of the earth; (compare Gen. i. 29 with Gen. i. 30). Whether, if man had abode in the state of innocency in which he was created, thorns and thistles had not been, or the cereals had grown otherwise than they do, we are not informed, nor have we any data to go upon relative thereto. But now they are his for his meat on this one condition, that he sow them with his own hand in ground which his own hands have tilled; and such they have been in all his history that appears. “*In the sweat of thy face shalt thou eat bread*,” were the words spoken to him with reference to them after his fall—words true to this day—and scarcely uttered it would seem, with the addition, that “*in sorrow*” he should eat of that bread, when the Lord sent him forth from the garden of Eden to till the ground.

To sum up. Of the facts as to cerealia, this is the substance:—Cultivated varieties naturally, abnormal, monstrous states of some unknown and no where existing species of natural grasses (so the botanist, in words odd enough, gives expression to the fact).—\*they do not, as do the cultivated varieties of other natural plants, tend to revert back to their wild state, and thereby become, to man at least, and as regards his food, worthless. Such as they are essentially, in that

\* “Cultivated varieties of some unknown species, perpetuated as races.” “Wheat is an abnormal state of some plant.” “We are at a loss to know the original types and species.” —BALFOUR’S *Class Book of Botany*, p. 708. “The native countries of our more important cereals, or corn-producing plants, are altogether unknown.” —(BENTLEY’S *Manual of Botany*, 1861, p. 697.) “The corn-plants, such as they are found under cultivation, do not grow wild in any part of the world.” —(KNIGHT’S *Food of Man*, vol. i. p. 22.)

state they abide permanently. Again, bearing seed only, bearing no buds, they are strictly annual plants, growing up year by year from seed, and growing in no other way. Yet, withal, they do not grow, as do other annuals, of their own accord, or by the natural dispersion and germination of their seed. Cast on themselves, left to nature, they quickly disappear before the perennial wild plants and become extinct. The one condition of their permanency in the world; of their diffusion; of their growth in quantities adequate for man's needs,—a condition of existence, as we have said, peculiar to them, is, that they be sown of man in ground carefully prepared by him for them beforehand and duly fitted to receive them.

Can it be that any one, duly reflecting on the facts now stated in regard to the cerealia, should fail to see—*first*, that nature never could have provided or have preserved these plants for man; and, *secondly*, supposing as we must, the cerealia and man to have been coeval, that if man had been himself beholden to nature *alone* for what he is,—if, under her, he were and had been the *sole* architect of his fortunes in the world, the cerealia must have passed away and been lost to him, irretrievably and for ever, long before he could have raised himself from a state of nature.

This being the case, the character of the "conditions of existence" of the cereals being such as we have affirmed, and man's natural ignorance of their use and value being such as the history of the savage tribes demonstrates,† it surely needs no argument to prove, that not only must these plants have been *specialy* created by God for man, and created, too, at the time when he brought man into the world, but that man himself must have been *directly taught* of God, as well as the use and exceeding value of them, as the way to grow them. The history given us in the book of Genesis, of their relation to man, and man's relation to them, as is that of the Creator's converse with man respecting both, is in fact such a history, short as it is, as our modern science, if true to herself, must needs accept as *genuine*. No account of the matter other than given by Moses, will explain the known facts of the case. Had God not specially created the cerealia, nature never would have produced them. Had God not said to man, "Behold, to you have I given them for meat," man never would have *discovered* while yet he had them, their use as food. Had God not sent

man forth to till the ground, acquainting him that thus only, even to the sweat of his face would the cerealia grow, there would at this present be no corn in the world.

Nay, but for this, there would have been no corn in Egypt, 3500 years ago, when God, of set purpose, "brake the whole staff of bread," and "famine was all over the face of the earth;" and when, nevertheless, of His great mercy—for His mercy endureth forever—He sent a man, even Joseph (sold to be a bond servant) beforehand into Egypt, who forewarned of Him, gathered up all the food of seven years of plenty which were in the land, laying up in the cities the food of the field which was round about every city; and who, when the evil days came, and the dearth was in all lands, and was sore and grievous, opened all the store-houses, and sold corn to the Egyptians, and to all countries which came into Egypt to him for to buy thereof: a time when Israel (in whose loins lay the promised seed, the desire of all nations), that he might *not die but live*, also came into Egypt, and Jacob sojourned in the land of Ham.

A time it was, when making His own cerealia, or one of them, namely wheat, the occasion, God turned the current of human affairs into a channel altogether new, making also Egypt the cradle, and the wisdom of the Egyptians the school, in which to raise up and to rear and civilize the children of Jacob, his chosen; while yet, by signs and wonders, *miracles*, which wrought among them, He made known to them, and to the Egyptians themselves no less—a people civilized were always slow at heart to believe, that verily there is a God that ruleth in the earth, the Lord of Heaven and earth, and that this God is one Lord.

And these times, and the wondrous things that were done during them, have descended even to us. We have heard with our ears and our fathers have told us, how, aforesaid in Egypt, God, by the hand of Joseph, saved man from perishing from famine, as once he perished by water; and how, beginning therewith and there, he opened a chapter in human history which is not yet finished. And if now, in these days, His strange work had ceased, and we see no signs and wonders visibly attesting His presence and His agency in the world, it is not as if they had never been; "They have left behind them a wake which still bears us along with it." Yet even as it is, as day by day we eat our bread with cheerfulness and singleness of heart, giving God thanks, we may see on that same bread, if we will but look, the impress of a *miracle*, and the attestation of a *providence*, both still in silent operation around us. And if so,—then, with this sense of *Real Presence* of God in our common bread, we shall feel it to be but a small demand on our reason to believe (to single out one of those early transactions) that by the space of forty years in the wilderness, wherein nothing

† "When some European missionaries introduced into New Zealand the culture of wheat, telling the Maories that bread is made of it, they were rejoiced, for bread, in the form of ship-biscuit, they had often tasted and much relished. But when the corn was tall, they dug some of it up, expecting to find eatable roots; and when they found only fibres, they thought the missionaries were making game of them. . . . The Maories had derived all their vegetable food from roots; and therefore naturally supposed bread to be made of roots. That little hard seeds were to be ground (a process they had never seen, or imagined), and the powder made into a paste with water, and then baked was what could never have occurred to them."—ARCHBISHOP WHATELY, *Lessons on Mind*, p. 118.

grew that man could eat, God *miraculously* fed his chosen people with manna; believing which, we may well believe also all else that we are told, and may read for ourselves in His blessed Word, as to the "wondrous works done by Him in the land of Ham, and the terrible things by the Red Sea," in behalf of a people whom He loved, and with whom were bound up His purposes of mercy to the whole family of man.—*Good Words.*

ALEXANDER HARVEY.

### Scientific Jottings.

The relations which exist between the natural sciences are, perhaps, greater than at first sight may appear: it is only after having made oneself somewhat familiar with most of the separate branches of physics, &c., that one is able to form an idea how closely they are related to the more strictly called "natural sciences," a chain of relationship connecting the whole, so that it is difficult to have even a good popular notion of the one, without some knowledge, however slight, of the others. As an acquaintance with these subjects is considered necessary to every man of a liberal education, and as the taste of the public is inclining so much in that direction now-a-days, it may not be uninteresting to take a short glance at the connection existing both individually and collectively, between geology, mineralogy, chemistry, crystallography, and biology, (both animal and vegetable,) and in as short and succinct a style as possible to impress on the reader of any of these divisions of natural history, that he should not, through any inclination towards one particular department, deprive himself of the pleasure of its application to the others; and, since *application* is the whole use of a practical science, that he should neglect no opportunity of bringing his knowledge of one branch to increase that of the others.

Take that wide and interesting study, geology, for instance, its study, however useful, without its great expounder palæontology, would be one of the tamest and most uninteresting, and its practical application nothing but the work of a digger or delver, save for the small light that would be thrown upon it by the minerals which you might meet, and which of themselves would be of little value but for the rigid chemical and crystallographic laws to which they are subject, and palæontology itself would be useless and mere guess-work—you might have piles of fossil shells, and slabs of fossil reptiles and animals which would surpass those in the British Museum, and had you not zoology to identify your remains, and comparative anatomy to correlate their structures, you would be simply in the dark as regards the great problem of geology, the advancement of life on the globe.

The most trivial and apparently despicable circumstances relating to animal life should not

be passed over heedlessly when you come to apply your mind to the great problems which will be laid before you; and the very best exercises to which the young student in geology can apply himself are the works of the most eminent labourer in this field of science—Professor Owen. He will see there that the work he has before him is not that which a young lady would adopt to pass away her time, but something like reality, which will require the whole of his energies, and good will to boot. Inferior, certainly to the remains of animal life, but still affording an immense amount of information as to the former condition of the world, both as to climatology and structure, the beds of fossil plants and trees require to be studied with even more attention, inasmuch as there is less known about them, and that little requires to be well improved before anything like a definite classification of the flora and fauna can be arrived at. Of course this is the highest perfection of botany, and on which the most eminent naturalists have been, and are engaged. Thus a very fair botanical range is to be attained, and will repay the trouble of gaining it, without fear of limitation as to the number and description of specimens.

Zoology and botany being generally studied together, each will contrast well with the other, and render the somewhat tedious labor, an agreeable recreation. The other ally of geology before mentioned, namely, mineralogy, is only another name for applied chemistry; and some of the nicest and most difficult operations in chemical analysis must be performed before we can tell the name of a mineral, which, perhaps, to all appearance is the same as one of our every day friends; besides, the subject of mineralogy in its present rather crude state is one which by itself will be found highly interesting, as in it every one can indulge his fancy on certain points which are not very definitely arranged, and in which speculations he may, by attention and study, both theoretical and practical, effect something which may really advance one of the most attractive subjects in nature.

The grouping of the various elements of minerals into their proper formulæ gives occupation to heads which in point of ability are second to none; while not one of those men whose names will be seen in every book on mineralogy could tell the composition of even the simplest granite which we kick along the road were it not for the assistance of a few agents and simple manipulative operations. Chemistry is so wide a subject, it would be out of our power here even to hint at even the heads of its many relations; but from what has been said above, it may be supposed that the study of chemistry is absolutely necessary to one who wishes to have an intimate acquaintance with the crust of the earth; and the advantages to be gained in every day life from an intimacy with chemical phenomena can only be appreciated by those who have received its benefits.

Physics, including in its wide range electrical and magnetical disturbances, changes and appearances, with the theory of heat and meteorology in their relations to chemistry, are most marked and intimate; a thorough knowledge of either demanding a fair knowledge of the other, some of the most fundamental principles in the former being totally inexplicable without the assistance of the latter, and *vice versa*.

From the very short sketch above given of a few of the relations of the natural sciences, it is evident that a subject so wide and so respectively intimate in relations should be pursued with a view to the ultimate end—an equal knowledge of them all.—*Irish Farmer's Gazette*.

REMINISCENCES OF SMITHFIELD.—About 1100, Smithfield was little better than a swampy meadow, where certain smiths and armourers had set up their shops and forges, on which account it early became a place of considerable resort; but, shortly after, Henry I. granted a charter for a Priory of Black Canons, under the guardianship of St. Bartholomew. It became yet farther frequented when Henry II. permitted the monks to hold a fair, for three days annually, which ultimately grew into an important commercial gathering, as well as the occasion of general festivity. To the fun and frolic of the fair we may make allusion hereafter, but shall at present confine ourselves to the more serious incidents of the Smithfield chronicle. The open space afforded here to the Londoners was, for several centuries, used by them, in common with Finsbury-fields, for archery and athletic sports generally. Nearly all the Court military holidays were held here. Scarcely a tilt, joust, or tournament came off in any other quarter of the town, for it pleased the citizens to witness such scenes, and their presence made them more impressive. Appeals to the judgment of God were often decided here; and the ordeal by fire and water was of daily occurrence, as well as the duel, or kamp fight of the Saxons. We have alluded to the great Edward's presence here, after the victory of Cressy; and, in 1374, when he had fallen into "second childishness," though only in his sixty-second year, infatuated by the charms of Alice Pierce, he brought her hither in a splendid open car, sitting by her side; and calling her the "Lady of the Sun," he conducted her to the lists, followed by a train of knights, each leading by the bridle a beautiful palfrey, mounted by a gaily dressed damsel. This festival lasted seven whole days, and, according to the annalists, was marked by the most profligate expense. Here, too, his grandson, Richard II., held an unusually magnificent tournament, early in his reign. "There issued out of the Tower of London," says Froissart, "first, threescore coursers, apparelled for the jousts, and on every one a squire of honour, riding at a soft pace; then issued out threescore ladies of honour, mounted on fair palfreys, and

every lady led a knight by a chain of silver, which knights were apparelled to joust." Certainly the dissipation of those early times was partly rendered excusable by a spirit of gallantry and unselfishness. The gentry of the land, and even the merchants and workers of London and the great towns, were all deeply imbued by a love of warlike exercises, not unmixed with a chivalrous generosity which made English warriors the admiration of the world. We need only refer, as a proof of this, to the conduct of the Black Prince to his prisoner, King John.—*City Press*.

SHOES.—It is amazing the misery the people of civilization endure in and from their shoes. Nobody is ever, as they should be, comfortable at once in them; they hope in the long-run, and after much agony, and when they are done, to make them fit, especially if they can get them once well wet, so that the mighty knob of the big toe may adjust itself and be at ease. For my part, if I were rich, I would advertise for a clean wholesome man, whose foot was exactly my size, and I would make him wear my shoes till I could put them on, and not know I was in them. Why is all this? Why do you see every man's and woman's feet so out of all shape? Why are their corns, with their miseries and maledictions? why the virulence and unreachableness of those that are 'soft'? Why do our nails grow in and sometimes be torn violently off? Why are shoes so dear? All because the makers and users of shoes have not common sense, and common reverence for God and his works enough to study the shape and motions of that wonderful pivot on which we turn and progress. Because Fashion—that demon that I saw dressed in her own crinoline, in bad shoes, a man's old hat, and trailing petticoats, and with her, (for she must be *her*) waist well nipt by a circlet of nails with the points inmost, and any other of the small torments, mischiefs, and absurdities she destroys and makes fools of us with,—whom, I say, I wish I saw drummed and hissed, blazing and shrieking out of the world,—because this contemptible slave which dominates over her makers, says the shoe must be elegant, must be so and so, the beautiful living foot must be crushed into it, and human nature must limp along Princess Street, and through life natty and wretched. It makes me angry when I think of all this.—*Dr. John Brown*.

THE CAT AND SPARROW.—A cat caught a sparrow, and was about to devour it, when the sparrow said: "No gentleman eats till he washes his face." The cat, struck with this remark, set the sparrow down, and began to wash his face with his paw, but the sparrow flew away. This vexed puss extremely, and he said: "As long as I live, I will first eat and wash my face afterwards," which all cats do to this day.

NOT A BAD MISTAKE.—We have seen some awful typographical errors in our day and generation, but seldom any more absurd than the following. An editor, wanting a line to fill up a column, gave:

"Shoot Folly as she flies."—POPE.

In setting up the above, the printer had it thus:

"Shoot Polly as she flies.—POP!"

## International Exhibition, London, 1862.

THE Commissioners for Canada at the INTERNATIONAL EXHIBITION of 1862, give notice to all parties desirous of exhibiting Canadian products, whether application has been already made for the exhibition of the same or not, that such articles may be sent in for examination and approval to the following places, at any time between the TENTH DAY of FEBRUARY next, and the undermentioned dates, viz:—

IN CANADA WEST.—London, 18th February; Hamilton, 20th February; Toronto, 22nd February; Kingston, 25th February, and Ottawa, 28th February.

IN CANADA EAST.—Quebec, 14th February; Three Rivers, 18th February; St. Hyacinthe, 22nd February; Sherbrooke, 25th February next; and Montreal, 3rd and 4th March next.

Articles will be received and stored at the Depots of the Grand Trunk Railway Company at London, Toronto, Kingston, Quebec, Point Levi, Sherbrooke and St. Hyacinthe.

The Commissioners will begin their examinations at 10 o'clock, A. M., of each day named.

Intending exhibitors must deliver the articles for exhibition at the above named places, free of charge. Should they not be approved, the Grand Trunk Railway will return them free of charge, to any depot on their line from which they have been sent.

Parties sending in Grain or Woods are requested to transmit a certificate, stating the species and varieties, and where grown. Woods should be sent of the usual dimensions for commerce, and Her Majesty's Commissioners have expressed a desire that they be shown in planks 4 inches thick, showing the sap on both sides, or in 4 inch scantling, and accompanied, wherever practicable, by twigs with leaves or flowers.

Parties desirous of further information, may apply, concerning Minerals and Specimens of Economic Geology, to Sir W. E. Logan, Montreal; concerning products of the Forests and Waters, to Dr. Tache, Quebec, or Dr. Hurlburt, Hamilton; concerning Agricultural produce, to Hon. L. V. Sicotte, St. Hyacinthe, and Col. Thomson, Toronto concerning articles of Canadian Manufacture, to Dr. Beatty, Cobourg, or to the Secretary, Montreal, to whom also, communications on all other business of the Commission are to be addressed.

R. CHAMBERLIN, Com'r, Secretary.

Montreal, December 12, 1861.

## BOARD OF AGRICULTURE.

THE Office of the Board of Agriculture has been removed to 188 King Street West, a few doors from the late location adjoining the Government House. Agriculturists and any others who may be so disposed are invited to call and examine the Library, &c., when convenient.

HUGH C. THOMSON,  
Secretary.

Toronto, 1861.

## Notice of Co-Partnership.

THE Undersigned have entered into Partnership as Seedsmen and dealers in all kinds of Agricultural and Horticultural Implements, under the firm of James Fleming & Co.

JAMES FLEMING,  
GEORGE W. BUCKLAND.

## NOTICE.

JAMES FLEMING & CO., Seedsmen to the Agricultural Association of Upper Canada, will carry on the above business, wholesale and retail, at 126 Yonge-st., 4 doors North of Adelaide-street, until next July, when they will remove to the new Agricultural Hall, at the corner of Queen and Yonge-streets.

JAMES FLEMING will continue the business of Retail Seedsmen and Florist at his old stand, 350 Yonge-street.

Toronto, January 1st, 1861.

## FOR SALE.

AT

WOODHILL, WATERDOWN P. O.

MR. FERGUSSON expects to have several pure *Durham* bull calves to dispose of next Spring, 1862, not intending to raise any this season. These calves will be all of the well known *DUCHESS* tribe, and will be put on the G. W. R. R. at six weeks old for eighty dollars each.

N. B.—First come, first served.

Waterdown, Nov. 14, 1861. 4-t.

## THOROUGH BRED STOCK FOR SALE.

THE SUBSCRIBER has for Sale Durham and Galloway Cattle, male and female. Leicester, Cotswold, and Lincolnshire Sheep, male and female.

January 1, 1862.

JOHN SNELL,  
Edmonton, P. O., C. W.

tf.

**VETERINARY SURGEON.**

**A**NDREW SMITH, Licentiate of the Edinburgh Veterinary College, and by appointment, Veterinary Surgeon to the Board of Agriculture of Upper Canada, respectfully announces that he has obtained those stables and part of the premises heretofore occupied by John Worthington, Esq., situated corner of Bay and Temperance streets, and which are being fitted up as a *Veterinary Infirmary*.

Medicines for Horses and Cattle always on hand. Horses examined as to soundness, &c.

Veterinary Establishment, Corner of Bay and Temperance Sts.

Toronto, January 22nd, 1862.

**FOR SALE.**

**A FEW PURE-BRED SOUTH-DOWN RAMS**  
and Ewe Lambs, from

**IMPORTED STOCK,**

Selected from the Best Flock-dealers in Dorset, Wilts, and Hants.

The Subscriber will Warrant these Lambs to produce as much Wool and Mutton, and of equal Quality, as those of Jonas Webb, or any other Flock of the same kind and number in England.

JOHN SPENCER,  
Brooklin, Post Office,

Oct. 12th, 1861. Ontario County C. W.

OR

JOURNAL AND TRANSACTIONS OF THE BOARD OF AGRICULTURE  
OF UPPER CANADA.

VOL. XIV.

TORONTO, FEBRUARY 16, 1862.

No. 4.

**The Board of Agriculture.**

From the following official notice, which we cut from the *Canada Gazette*, it will be seen that the members of the Board of Agriculture of Upper Canada whose term of service expired at the commencement of the year, have been re-elected by the county societies—

*Bureau of Agriculture and Statistics.*  
Quebec, 14th February, 1862.

The following gentlemen have been elected members of the Board of Agriculture in Upper and Lower Canada for the present year.

UPPER CANADA.—R. L. Denison, Esq., E. W. Thomson, Esq., Hon. G. Alexander and Hon. H. Ruttan.

LOWER CANADA.—Dr. J. C. Taché, B. Pomroy, Esq., O. E. Casgrain, Esq., Hon. P. A. Archambault.

A. CAMPBELL,  
Acting Secretary.

**Fruit Growers' Association.**

We have to thank the able Secretary of the Upper Canada Fruit Growers' Association, D. W. Beadle, Esq., of St. Catharines, for the very interesting report of a recent meeting of the Association at Hamilton, which will be found in another portion of the Journal. We would beg leave to request particular attention to the series of questions addressed by the Association to Horticultural and other Societies and individuals, asking for informa-

tion in regard to the success attending the experiments made in the cultivation of the different varieties of fruit. Full and careful answers to these questions from all parts of the Province would be of great value and importance, not only to those who wish actually to engage more or less extensively in fruit culture themselves, but also to every one interested in the progress and amelioration of the Province.

**Address of Condolence to Her Majesty.**

The following is a copy of an Address of Condolence to Her Majesty the Queen, on the occasion of the deeply lamented death of His late Royal Highness the Prince Consort, drawn up in accordance with the resolution passed at the Convention of the Agricultural Association held in this city on the 30th January last, and which has been transmitted to His Excellency the Governor General, to be forwarded to Her Majesty.

TO THE QUEEN'S MOST EXCELLENT MAJESTY.

We your Majesty's most dutiful and loyal subjects, the Agricultural Association of Upper Canada, desire to offer to Your Majesty the assurance of our devoted attachment to your throne and person, and of our deep and respectful sympathy with your Majesty in the great affliction which has befallen your Majesty and the British nation in the early and lamented death of His Royal Highness the Prince Consort.

While we deplore in common with all our

fellow subjects in every part of the Empire, the death of a Prince so distinguished by rare intellectual gifts and eminent virtues, we feel that his loss will be more especially deplored by those Societies in our father land which, like this Association, have for their object the advancement of agricultural science.

To the distinguished patronage and enlightened judgment of His Royal Highness, was due much of the wonderful development and rapid progress which have so particularly distinguished British agriculture within late years.

Nor can we forget, that the Royal Agricultural Society of England has, by his lamented death, been deprived of the invaluable counsel and direction of a President, whose special knowledge of the subjects embraced within the sphere of the Society's labours, and varied acquaintance with the Industrial arts in general, rendered his presence in the chair of invaluable moment to the Society and the country at large, during this important year.

We would humbly express the hope, that the affectionate appreciation of His Royal Highness's many and exalted virtues entertained by all classes, and the loving sympathy of your Majesty's loyal subjects in this as in all other parts of your Majesty's dominions, may in some measure assuage the intensity of your Majesty's affliction. And we fervently pray that Almighty God may of His grace and goodness, support and comfort your Majesty and your Royal family, and that your Majesty may long be preserved to reign over the great Empire committed to your charge.

(Signed) E. W. THOMSON,

*President Board of Agriculture, Chairman.*

Toronto, January 30th, 1862.

### Flax Culture.

LONDONDERRY, Jan. 27th, 1862.

*To the Secretary of the Board of Agriculture.*

MY DEAR SIR,—Since my arrival in Ireland I was glad to find the prospects of the linen trade had very much revived. The very high prices cotton has reached within a few months no doubt was the cause of this, and the demand for flax, and desire on the part of the manufacturers for its cultivation in any country where they may be able to obtain it quite equal to last year, when I was here a little after this time. It was most fortunate we had not got the scutching mills the government had ordered before I came, as the Messrs Rowan Bro. & Co. have made a great improvement in them since, and they are now beyond a doubt the best mill, taking into consideration the saving in skilled labor, in Ireland. Parties have been here from Courtrie and tested them, and have ordered twenty of

them to be forwarded immediately. The six for Canada I hope to get shipped by the steamer of the 13th proximo, and will also endeavor if possible to get a hand sent with them or soon after who will understand setting them up and attending them. Too great efforts cannot be used to get the farmers to sow flax this season, the prices being at present and likely to be most remunerative. No effort should be wanting on the part of the active members of the Agricultural Societies throughout the country to encourage the farmers to sow all they can this coming spring, and it is well for those to know who may not be near a mill for a season or two, that as soon as they take the seed off, and have the straw properly dried on the grass, they may safely stack it up, put into any shed or barn, only keep it dry, and the fibre will improve the longer it is kept in this state, in truth for years. The prices too of Riga seed are advancing, from the great demand at present. It is worth in this market 43s. sterling per barrel of about 4 bushels, and it is expected it will be 50s. before sowing time. Should any one near Toronto wish to send for what they may require your enterprising townsman Rice Lewis, Esq., said he would import whatever he thought would be required for this spring's sowing; but parties in Guelph, Woodstock, and other places who have taken a lively interest in the cultivation of flax, intended when I left to forward an order here for what they wanted, and I would take care fresh seed was chosen for the purpose.

I am glad to say that it is thought here and in England that we will have no war.

The prospects for emigration this season much better than I expected.

Yours most truly,

JOHN A. DONALDSON,

*Canada Government Emigrant Agent.*

### Rowan's Flax Scutching Machine.

We give the subjoined wood engravings to represent this machine, several of which our government are about importing for the use of cultivators of flax in this province. We beg to refer to a communication from Jno. A. Donaldson, Esq., our energetic emigration agent in Ireland, on the subject in this number of our journal. The growth of flax will doubtless attract a largely increased share of attention this spring, and we shall make it a point to give all the information in our power on the subject. The subjoined description is from the *Mechanics' Magazine*, published in England.

## ROWAN'S MACHINE FOR SCUTCHING FLAX &amp;c.

This invention, introduced by Messrs. J. Rowan & Sons, of Belfast, consists in scutching flax, hemp, and other fibrous materials by means of a revolving cylinder fixed in a frame round which cylinder are placed combs and beaters, and to which the flax or other fibrous material is pressed by the hand through an opening provided for the purpose in the front of the machine. After having been sufficiently acted on, the flax is withdrawn and reversed end for end; this done, it is then put through the same operation, when it is finished. Sometimes rollers are used to pass the flax or hemp into the machine.

FIG. 1.

FIG. 2.

FIG. 3.

FIG. 4.

Fig. 1 of the accompanying engravings is a partial side elevation, and Fig. 2 a plan of the machine.

*a, a*, is the revolving drum or cylinder mounted on a shaft or spindle *g*, and fitted with a comb *h*, and with beaters *s, s*, round its periphery. One comb and five beaters, are found to act well, but the number of either may be altered. Figs. 3 and 4 are views on an enlarged scale in front elevation, and plan, of a comb detached. *B* is a side or framework enclosing the upper part of the drum; *C, C*, are louvre plates inclining downwards to allow of the broken boon or woody particles detached from the flax or other fibre under treatment passing off freely, and being blown down to the floor by a current of air passing from the cylinder through the louvres. The object of the louvres is to prevent the boon getting embedded with the fibre. *D* is the feeding board; it is made as shewn to enable the attendant to feed and handle the straw and flax during the operation with safety. A set screw is connected to the plate *b* for the purpose of regulating the distance thereof from the comb and beaters, which distance requires to be modified according to the nature of the fibres being operated on. *F* is the front plate of the louvre casings, *c, c*, are passages or channels by which the boon is led to the openings *e, e*, through which it falls to the ground; *ff* are fast and loose pullies mounted on the spindle *g*. The flax, hemp, or other material to be scutched is fed by the hands of an attendant to the drum or cylinder by means of the board *D*, and is submitted to the action of the comb and beaters; the material is allowed to pass on into the machine until one hand of the attendant comes nearly in contact with the front plate *F*, when the materials is withdrawn, turned upside down, re-inserted, and submitted to the same operation, and so on until it is sufficiently scutched.—*Mech. Mag.*

### Importance of Birds to Growing Crops.

20, DANIEL ST., BATH, Jan. 29, 1862.

To George Buckland, Esq., Professor of Agriculture, Toronto.

DEAR SIR,—In looking over my memorandum book the following slips respecting the usefulness of birds in destroying insects, cut from newspapers, is sent for your information. If the information be not in your possession, please give it a corner in the Upper Canada *Agriculturist*.

1st slip.—*Birds and Insects*.—At the late Agricultural meeting at St. Gallen, Switzerland, Baron Von Tschudi, the celebrated Swiss naturalist, dwelt on the important services of birds in the destruction of insects. Without birds, said he, no agriculture and vegetation are possible. They accomplish in a few months the profitable work of destruction which millions of human hands could not do half so well in as many years; and the sage, therefore, blamed in very severe terms the foolish practice of shooting and destroying birds, which prevails more especially in Italy, recommending on the contrary the process of alluring birds into gardens and cornfields. Among the most deserving birds he counts swallows, finches, titmice, redbills, &c. The naturalist then cites numerous instances in support of his assertion:—In a flower garden of one of his neighbours, the trees, all rose-trees, had been suddenly covered with about 2000 tree lice. At his recommendation a marsh titmouse was located in the garden, which in a few hours consumed the whole brood, and left the roses perfectly clean. A redbill in a room was observed to catch about 900 flies in an hour. A couple of night swallows have been known to destroy a whole swarm of grubs in 15 minutes. A pair of golden crested wrens carry insects as food to

their nestlings upon an average 36 times in an hour. For the protection of orchards and woods titmice are of invaluable service. They consume in particular the eggs of the dangerous pine spiders. One single female of such spiders frequently lay from 600 to 800 eggs twice in the summer season; while a titmouse, with her young ones, consume daily several thousands of them. Wrens, nuthatches, and woodpeckers often dexterously fetch from crevices of treebark numbers of insects for their nestlings.

2nd. As a proof of the valuable services rendered by swallows it is estimated that one of these birds will devour 900 insects in a day, and when it is considered that some insects produce as many as nine generations in a summer, the state of the air, but for these birds, may be readily conceived. One kind of insect alone might produce 560,970,489,000,000 of its race in a single year!

3rd. A gentleman in the County of Kent, England, writes thus:—I have excellent means of knowing that in various parts of the county, whole crops of fruit, vegetables, and grain have been swept off entirely by various kinds of minute insects, which the birds alone are competent to detect and destroy, and which not one man in a hundred knows anything about. Men see their hopes blasted, but they believe some ill wind has blown "a blight," for under that vague term they designate all such evils. In no localities have insects done so much injury to the fruit where birds are indiscriminately and systematically exterminated. The gardens in some localities are planted with plum trees. In 1858 they promised an extra abundant crop, but long before the fruit was matured the havoc of the winter moth, upon which the birds, especially the titmouse, feed, consumed almost the entire crop.

May not the foregoing statements relating to the interesting subject of protecting and encouraging the introduction of small birds into the growing and improving Province of Canada be a fit subject for the consideration of the Board of Agriculture? Perhaps a more favourable opportunity for procuring three or four species of birds will not again occur as at the forthcoming National Exhibition to commence in England next spring, where a great variety of birds will be collected, and all the bird fanciers and dealers in England may be consulted. The Commissioners deputed to proceed to England at the Exhibition, might be authorized to purchase and bring out some birds, to be let loose in the city of Toronto, where they would be protected for a while in the large gardens and pleasure grounds within the limits of the city, the increase would hereafter migrate through the country, and become exceedingly useful in the destruction of insects. The expense would be small, and the benefits arising from the introduction of the birds would be beyond any

present computation. Only one kind or variety should be placed in each coop, or cage, during the voyage. I am, Sir,

Your faithful servant,  
J. B. MARKS.

[It affords us much pleasure to insert the above very interesting communication from an old and zealous friend of Canadian Agriculture, who, though at present widely removed from us, continues to cherish an unabated interest in the welfare of this new country, in which for many years he permanently resided. We commend the subject of Mr. Marks' letter to such of our farmers and gardeners especially, as take a practical interest in those branches of Natural History to which it more immediately relates. Considerable success has already attended the introduction of several species of British birds into the Australian colonies; and if similar attempts were made in these parts of the American continent, due attention must be paid to the length and severity of our winters. The reckless destruction of birds is no doubt as impolitic as it is inhuman.—Eds.]

### Comminuted Food.

[From the Irish Farmer's Gazette]

Sir,—I am induced by your confessing in your issue of the 18th ult. "to feel great interest in the experiment" of using "comminuted food" to trouble you with my experience of the system. In 1860 I had, in every sense of the word, a very small turnip crop; but having a chaff-cutter and one of Bental's most excellent root pulpers, I determined to try the plan of giving the turnips pulped and the hay chaffed and mixed together to my stall-feds, numbering 20 beasts. Both machines were worked by manual labour, and the food prepared every day. So well pleased was I with the result that I made up my mind to erect a "one-horse gear," by which I would be enabled this year to work the two machines together, and on a much more extensive and more economical scale. The horse gear cost £10, exclusive of the expense of setting it up, which was trifling. 40 beasts are fed three times daily on the "comminuted food," besides 50 sheep that are fattening, and 8 farm-horses have their haychaffed. The cattle get all their hay through the turnips, except a little at night. It takes a horse about 2½ hours daily to do the entire work. The great advantages of the system are, firstly, from the ease with which the cattle consume the prepared food, additional time is gained between each feed for rest, besides the saving of muscular exertion necessary to enable a beast to get through a feed of whole swede turnips, which is

certainly considerable; secondly, the great saving of food, as there need never be a pound of waste; and thirdly, the increased facility afforded for consuming profitably the straw that can be spared from litter. Each of these advantages tends in itself to enable the farmer to keep more stock upon the same amount of food; for, owing to the first, cattle *unquestionably thrive more rapidly*; and, consequently, require shorter keep to prepare them for the butcher; the food saved from waste in the second; and in the third, from passing your straw through the chaff-cutter, and thereby using it in the most economical manner, you can do with less hay, and have more of your land free for stock in the summer months. There are other advantages I may mention. Cattle, stall-feeding, are never in danger from choking, and lambs and hogget cheep can eat the pulped roots freely. I am giving my stall-fed cattle a mixture of rape, bean and Indian meals, besides a little crushed oats daily, at a cost of 10s. per mouth. I have a portable 16 gallon boiler with steamer attached. The boiling water is put into a wooden vessel, and the Indian and bean meals stirred into it; as soon as the next boiler is ready, which very shortly occurs, it is poured on the previous mess, and the rape-meal added, and stirred for some minutes. This gruel is then carefully poured over the chaffed hay and bruised corn, thoroughly incorporated with them, by means of a three-pronged fork. The mess is then closely covered up for next day's use, and given at the noon feed, after about half allowance of roots. It is then blood warm, has a very fragrant smell, and is relished by the cattle. I think it a great advantage to use the boiling water. Last year I gave bean meal uncooked, and frequently observed it passed by the animals in their evacuations just as they had eaten it. I never perceive that now. Not having straw to spare this year from litter, I have not derived all the advantages I expect in future from my system. I commenced some time back to give my horses steamed turnips at night through thin chaffed hay and bruised corn. Previous to my doing so, they looked very poorly, though getting a full allowance of corn, and chaffed hay *ad libitum*. Since I have given the turnips they have thriven apace, and are now in a first-rate condition.—Yours, &c., A YOUNG TENANT FARMER.

### Professor Buckman on Meadows and Pastures.

[Lecture before the Farmington Agricultural Library, Berkshire, England.]

Professor Buckman said the subject which he was called to lecture upon to them that afternoon was the "Natural History, Economy, and Treatment of Meadows and pastures." The subject was so wide that it was impossible he could enter into its discussion in detail, because to do so

would be absolutely necessary to give some description of the anatomy and structure of grasses. On the present occasion he must leave out that portion of the subject, and give them some notion of the history, economy, and the different modes of treating meadow land. He would take it for granted that all farmers were fully impressed with the importance of the subject. When they considered how much of the land of this country was in pasture, and remembered the fact that "the man who made two blades of grass grow where only one grew before was a benefactor to his country," it behoved all of them to see whether they were making the best use of their meadow and pasture land—whether it was not possible to make more and better grass grow than heretofore. In arable cultivation they all knew that it had advanced so rapidly that, perhaps they now got something like double the produce they obtained from the same quantity of land fifty years ago; whereas in grass land it was generally admitted that they were rather behind, and that they did not do so well as they formerly did. There were a great number of reasons for this. The farmers had not studied the natural history of the grasses of which meadows were made. To compare England with other countries, they must come to the conclusion that the great glory of this island was its meadows and pastures; for there was no country in the world that could boast such meadows, but they were just beautiful and productive in proportion as they were cared for and attended to.

#### NATURE OF GRASSES.

In alluding to the changes which took place in meadows under different circumstances, he said that in adjoining parishes and districts there was evidently a great difference in the meadows, some being comparatively worthless, while others close at hand yielded a great amount of produce. If they looked at the nature of the grasses they would find them a most wonderful kind of plant. There were 150 species of grass in this country which adapted themselves to every circumstance, and just in proportion as they neglected the pasture would a great number out of those 150 begin to grow and take possession of the land; and as the greater number of our grasses were what was called sour grasses, the land became full of sour grass. On the other hand, when they found a good pasture, they would find it consisted of a few species of the right sort. The effect of care in cultivation was to kill the sour grasses. He could tell the condition of a pasture by the grass which was found upon it; those who studied the nature of grasses could tell not only the nature of the subsoil, but also the cultivation of the surface soil. Wherever they saw a quantity of wild barley, it was very prejudicial to the hayrick, as its long spikes or prickles so irritated the mouths of cattle that they could not eat, and consequently such hay was not only bad, but almost useless. It was found that long

broom grass always grew on limestone. He had seen a field where there was none of it growing except where some lime had tumbled down the side of the bank, so that by the broom grass they could tell where there was limestone with the greatest possible accuracy.

#### CULTIVATION OF MEADOWS.

With regard to the cultivation of meadows, he would premise by saying that they required cultivation as much as arable land. There was not the same amount of work or expense required, but they must be cultivated, and an intelligent mind only could get the best out of them. It was too much to expect that pastures would yield a good produce spontaneously, without wanting anything done to them: what would occur if left to themselves? The birds would carry haws, andsloes, and other seeds, and the pasture would become a wild jungle. The only got their beautiful meadows by dint of careful cultivation. But generally they were not carefully enough cultivated, and he would point out the following conditions necessary to the proper cultivation of meadows:—If any one acquainted with the grasses would go over a meadow, he would soon find out whether it was dry or properly drained. If he found a quantity of those “bullpates,” as they are called, or large hassocks of grass, there there must then be a quantity of water, and if the land were drained all that would die out very quickly. There were a great number of grasses which could only grow under wet conditions, and as soon as the land became dry they died out as quickly as possible, leaving only a blade here and there, and then, supposing the drainage to get out of order, they would immediately see these single blades multiply, and the meadow resume its former state. With reference to irrigated meadows, most of them knew that a very great increase was given to the yield of pastures in this country by letting the water run over them wherever circumstances permitted it. In order to do this properly they must have plenty of water, and facilities by which that water could be got upon the meadow, and equal facilities for getting it off again. The meadows should not be flooded, but the water should run over it so that it would percolate through the roots of the grasses. Wherever this was done, the results were extraordinary, and land which would not be worth £1 an acre was made worth £5 an acre. If the water were allowed to stagnate after the flooding, and they had not proper drainage, then they would have the evil results of the growth of sour grasses. The man who was called “the drowner” ought to know when the water was perfectly drained off, as he would be sure to see these sour grasses increasing if it were not. Draining was as absolutely necessary for pastures as for arable land, but fewer drains would be required generally for the former than the latter; where they wanted to have anything like a perfect pasture, they should have nothing like stagnant water on the land. Ano-

ther important point was the rolling. Our pastures were only in a good condition when there was a uniform texture caused by the mixture of grasses. If the grasses were allowed to grow in patches here and there, then they began to grow wild, and like what was seen in the jungle. Rolling prevented this, and the more a pasture was rolled the better it became. There was nothing like exercise for it; and to prove this, he instanced Oakley Park, where the militia were trained day after day, and, instead of doing any mischief, they did an enormous amount of good to the pasture. It caused a mixing of the grasses, and they grew up together much more easily and evenly after such exercises as this. Harrowing was also a point that should be attended to, in order to prevent an accumulation of moss, and to clear away the decayed grasses which had been allowed to stop behind. If not, they would have a peaty kind of soil, which they should endeavour by all means to prevent, and where it existed to get rid of; for the grasses which grow in peaty soils were not the most nutritious, and therefore anything like a peaty condition, or decaying vegetable matter, should not be allowed on the meadow. Far better to take away all the grasses and sow new seed than to skim the land over lightly, and leave behind that which would produce peaty conditions. There were some meadows adapted for pasture and pasture only, and were not satisfactory for making hay. Only a few years ago he was on the estate of Mr. Barker, of Gloucester, and in taking a ramble across the country, in the Home Park, he met with a quantity of grasses, of which he took the name, and Mr. Barker asked him what he thought of the value of the land, and he told him it was exceedingly good for pasture, but not for hay-making. Mr. Barker said it was very curious that his own bailiff should tell him that from practical experience, and that he, (Professor Buckman) should tell him the same thing from examining the grasses. There were a number of species of grasses, the hay of which would not be nutritious. Some had long spikes when full grown, like barley and wheat, and this was always objectionable in hay, so that here one was enabled, merely by the grasses, to point out something of practical importance.

#### FOLDING ON MEADOWS.

With regard to the amelioration of pasture by “folding,” he would make a few remarks. This was a subject to which he had paid particular attention. If they went on constantly feeding from a meadow with cows or sheep, and did not take hay from it, it would, under such circumstances, be very slow, indeed, to deteriorate. In fact, farmers very generally conclude that letting sheep upon the pasture was the way to revive it, however much deteriorated before. Year after year some carted away hay from the meadow, and returned no manure, but to compensate for that, they folded sheep upon it, as there was

some sort of notion that there was a great virtue in sheep to restore pastures. There was no innate virtue in sheep to do this, but there was a virtue in time—time allowed portions of the grass to be decomposed, and fresh food was thereby given for the other grasses to grow upon. It was quite true that sheep-folding did an amount of good, but the sheep added no new food, and it was folly to say that they added manure. What they did was simply this; they returned that grass which they ate, in a new form, and in that form it was food, but there was nothing new added. If they constantly fed cows upon meadows in that way, it would for a time get better than what it had been, but it would eventually get worse, and he would give an instance of this:—In Cheshire, where a most remarkably good cheese was made, he found ten years ago the meadow full of rushes and sedges, grasses with hollow and triangular stems, and exceedingly rough pasture. Sedges grew for the most part in wet sands. He found that the people had been constantly exporting an immense amount of cheese and the flesh and bones of cattle, and the result was that the meadows were constantly getting poorer. The phosphate had been taken out of the land and converted into the bones of the cattle, and then the sedges came up in the impoverished condition of the land, and replaced the true grasses, which required better food. In order to remedy this, the farmers in Cheshire—which is a great country for salt—put a quantity of salt over the meadows, and this killed every one of the rushes and sedges; and, as soon as the salt had dissolved the frame-work of these grasses, this formed a kind of manure, and refreshed the pasture again. But this refreshment was very much like that which was given by folding sheep—nothing new was added; they got no new conditions, and the meadows gradually relapsed into the same poor condition. But the Cheshire farmer now, to compensate for the bones and flesh which had been sent off the meadows in his cattle, was bringing back a compound containing similar materials—a guano which contained bone-dust in great quantities, and also a large amount of superphosphate, and they were using this to a larger extent than any other county in England, and the result was that the pastures were becoming thoroughly restored. Here, then, was the true theory of sheep-folding. They might bring a meadow into a certain condition by feeding sheep upon it, but it would not always remain in that condition. Whatever they took off it in the shape of mutton was so much impoverishment of the land. Whenever they wanted to restore a pasture in a very bad condition, they might very readily do it by taking the sheep from the turnip field towards evening, and folding them on the meadow the whole of the night. Then the sheep would bring something from the turnips, and add to the meadow new manure. There was no question they would do an enormous amount of good in that way.

#### HAY MAKING.

As regarded hay-making, they would get hay in quality and quantity just in proportion to the manure they put upon the soil. And if they took away hay, they must return something more than merely folding sheep upon the land in the usual way, otherwise the meadow would become impoverished. He would caution the farmers against letting the hay grow too long before making it. He was often told that there was no hay to make, and they must let it grow three weeks or a fortnight longer, in order to get a greater quantity. But, depend upon it, this was unwise. They should not let the grasses seed on any account. If they had not sufficient quantity previous to this, he did not think anything would increase it; but even if it did increase, the injury they would do to their pasture would be more than any benefit they would derive in the increase of hay.

*To be continued.*

#### Horticultural.

#### The Fruit Grower's Association of Upper Canada.

This association held its Annual Meeting in the City of Hamilton, on the 22nd and 23rd January 1862, which was very fully attended.

The President read a very interesting address on the objects and importance of this association.

On motion of D. W. Beadle, seconded by W. Holton, the thanks of the association were tendered to the President for his able and interesting address, and he was requested to furnish a copy for publication in the *Canadian Agriculturist*.

(A copy of the Address is subjoined.)

On motion of D. W. Beadle, seconded by Mr. Arnold, Mr. George Leslie was appointed a committee to obtain the publication of the President's address in the *Leader and Globe*, Toronto.

The association then proceeded to the election of officers for the ensuing year, with the following result:

*President*.—Judge Logie, Hamilton.

*Vice-Presidents*.—George Leslie, Esq., Toronto.—Alexander Leslie, Esq., London.

*Secretary and Treasurer*.—D. W. Beadle, Esq., St. Catharines.

*Fruit Committee*.—Messrs. Gray, Meston, Holton, Freed, and Laing.

*Publication Committee*.—The Secretary, and Messrs. Bruce and George Leslie.

Answers had been returned to the questions issued by the association from over thirty different parties, and these were now read by the Secretary.

After the reading was finished, on motion of Dr. Harburt, seconded by George Leslie, the

answers were all referred to the Secretary, with instructions to prepare a condensed report therefrom, and to submit the same to a special meeting to be held in the City of Hamilton, on the 20th of February, at 2 o'clock P.M.

On motion, the society now adjourned to meet at 9 o'clock, to-morrow, 23rd instant.

On re-assembling pursuant to adjournment the association took up the consideration of the Constitution and By-Laws, in accordance with the action had at the last January meeting and adopted the following,

### CONSTITUTION AND BY-LAWS

ART. I.—This Society shall be called "THE FRUIT GROWERS' ASSOCIATION OF UPPER CANADA."

ART. II.—Its object shall be the advancement of the Science and Art of Fruit Culture, by holding Meetings for the exhibition of Fruits, and for the discussion of all questions relative to Fruit culture; by collecting, arranging and disseminating useful information, and by such other means as may from time to time seem advisable.

ART. III.—The Annual General Meeting of the Association for the election of Office-bearers, shall be held in the city of Hamilton on the third Wednesday of January. Two other general Meetings shall be held at such places as shall be determined at the January Meeting, one on the third Wednesday in July, and the other on the second Wednesday of November, in each year.

ART. IV.—Its officers shall consist of a President, two Vice-Presidents, a Secretary and Treasurer, who shall be chosen by ballot, after nomination.

ART. V.—There shall be a general Fruit Committee, consisting of five members of the Association, to be appointed at the Annual Meeting in January, of whom three shall form a quorum.

ART. VI.—There shall be a Committee on Publication, consisting of not less than three members, who shall be chosen at the Annual Meeting in January.

ART. VII.—Any person may become a Member by an annual payment of One Dollar; and a payment of Ten Dollars at one time shall constitute a Member for life. The Presidents of all Horticultural Societies shall be, *ex-officio*, Members of this Association.

ART. VIII.—This constitution may be amended by a vote of a majority of the members present at any regular meeting—notice of the proposed amendments having been given at the previous meeting.

BY LAW 1.—The General Fruit Committee shall thoroughly investigate the subject of Fruit culture. It shall collect such useful and interesting information in reference to this subject it may be in its power, and accompany the same

with an Annual Report to the Association at the November Meeting.

2.—The Committee on Publication, to whom all the Reports of the Fruit Committee shall be referred at the November meeting, shall examine these Reports, and embody the information they contain in a general Report, to be submitted to the Annual General Meeting; and, after approval, cause the same to be printed in pamphlet form, for distribution among the Members.

3.—There shall be an exhibition of Fruits, and a discussion upon their properties, at each regular Meeting.

4.—The annual Subscription shall be due in advance, at the Annual January Meetings.

5.—The President, (or, in case of his disability, the Senior Vice-President,) may convene Special Meetings at such times and places as he may deem advisable; and shall convene such Special Meetings, at any time, on the written request of five Members.

6.—The President shall deliver an Address on some subject relating to the objects of the Association at the Annual General Meeting, and nominate members to fill any vacancy occurring in any office during the intervals between the Annual January Meetings.

7.—The Treasurer shall receive all moneys belonging to the Association, keep a correct account thereof, and submit the same at each January Meeting.

8.—A Committee of two shall be chosen at the November Meeting to audit the account of the Treasurer.

It shall be the duty of the Secretary to keep a record of the proceedings of the Association, conduct the correspondence, give not less than ten days notice of all Meetings to the Members; and specify the business of Special Meetings.

10.—At Special Meetings no business shall be transacted except that stated in the Secretary's circular.

11.—The order of business at the Annual Meetings in January shall be—1st, reading of Minutes; 2nd, reading of Reports of Officers and Committees; 3rd, delivery of Address by the President; 4th, Election or Appointment of the Officers and Committees; 5th, Miscellaneous Business.

12.—These By-Laws may be amended at the Annual January Meetings, by a vote of two-thirds of the Members present.

On motion of J. Bruce, seconded by Mr. Arnold, it was

*Resolved*,—That whereas Canada West is naturally one of the finest Fruit-growing countries in the world, and whereas it is desirable to offer every inducement possible to the development of this source of our wealth, therefore this association do suggest to the Board of Agriculture, that it is very desirable to increase considerably the premiums offered for "Horticultural Products," with a view of stimulating this branch of industry.

The secretary was requested to prepare from the Minutes of the Association, a list of the Fruits recommended for *general cultivation*, and of those recommended for further trial, and cause the same to be printed in the Canadian *Agriculturist* and other leading papers.

In obedience to this request the Secretary prepared the following :

LIST OF FRUITS RECOMMENDED BY THE  
UPPPER CANADA FRUIT GROWERS'  
ASSOCIATION.

APPLES

*For General Cultivation.*

Baldwin, south of the G. W. R. and Lake Ontario; Duchess of Oldenburg; Early Joe—as a dwarf for gardens; Early Harvest; Esopus Spitzenburg; Fameuse, or Snow-Apple—especially in the colder parts; Fall Pippin; Golden Sweet; Gravenstein; Golden Russet, as the best Russet; Hawthornden; Keswic Codlin; Northern Spy; Pomme Grise; Red Astracan; Rhode Island Greening, in the vicinity of the Lakes; Ribston Pippin; Roxbury Russet, for its long keeping qualities; Rambo, in suitable localities; St. Lawrence; Talman Sweet.

*For further Trial.*

Benoni; Belmont; Beauty of Kent; Colvert; Dominic; Fall Janetting; Jersey Sweet; Porter; Primate; Sweet Bough; Summer Rose; Swaar; Twenty Ounce Apple; Wagener; Westfield Seek-no-further.

PEARS

*For General Cultivation.*

Bartlett, south of the G. W. R. and Lake Ontario; Belle Lucrative, on quince stock; Flemish Beauty, on pear stock; Louise Bonne de Jersey, particularly on quince stock; Made line; Seckel; Tyson; White Doyenne.

*For further Trial.*

Beurre Giffard; Beurre d'Anjou; Duchess d'Angouleme; Osband's Summer.

CURRENTS

*For General Cultivation.*

Black English; Black Naples; Cherry; Red Dutch; Victoria; White Dutch; White Grape.

*For further Trial.*

Ogden's Black Grape; Prince Albert; Red Russian.

STRAWBERRIES.

*For General Cultivation.*

Burr's New Pine; Jenny Lind; Wilson, for market.

*For further Trial.*

Hooker; Monroe Scarlet; Trollope's Victoria; Triomphe de Gand.

RASPBERRIES

*For General Cultivation.*

Franconia; White Antwerp.

*For further Trial.*

Brinckle's Orange; Belle de Fontenay; Fastolf; Knevett's Giant.

GRAPES

*For General Cultivation.*

North of Lake Ontario and G. Trunk Railway; Clinton.

*For further Trial.*

Concord; Diana; Delaware; Hartford Proflice; Rebecca.

It was resolved that the association do hold its July meeting for 1862 at the town of St. Catharines, and its November meeting for 1862 at the city of Toronto, in consequence whereof the meetings for 1862 will be as follows:

On the 16th of July, at the Town of St. Catharines.

On the 12th of November, at the City of Toronto.

And it was also decided that at the next meeting in July, the association will discuss and determine the varieties of cherries, plums, and gooseberries best suited to our climate.

The association then proceeded to the discussion of grapes, as follows:

CONCORD GRAPE.

*Mr. Bruce*,—Had seen it only at Hamilton, it promised to be one of our favorite grapes.

*Mr. D. Murray*,—Is one of the most hardy; a fine berry and bunch, free from mildew, retains its berries, perfectly ripe on the 6th September for the last two years on open trellis, flavor superior to Isabella, is a strong free grower, ripens the wood well to the end of the shoots.

*Mr. Laing*,—Considered it one of the best, is hardy, and earlier than the Isabella.

*Mr. Arnold*,—It is perfectly hardy without protection, do not find it a strong grower nor great bearer, it ripens about a week before the Isabella, very pulpy with strong musky flavor and odor.

*Dr. Hurlburt*,—It bears well, ripens early, very little earlier than the Isabella, perfectly hardy, is grown by me on west side of building.

*Mr. Brennan*,—Is a valuable variety, good and hardy.

*Mr. Holton*,—The vine is quite hardy, a strong grower, think they did not ripen with me much earlier than Isabella, but the vine was neglected.

*Mr. A. Leslie*,—Has not fruited it, vine is hardy.

*Mr. G. Leslie*,—It ripens well in Toronto, is hardy and productive.

*Mr. Beadle*,—It ripens a week or ten days earlier than the Isabella, is very hardy and seems to be patient of abuse, neglected plants bearing good crops and ripening well.

**Mr. Freed**,—Considers it the handsomest and best black grape cultivated; ripe 25th Sept.

## CANADIAN CHIEF.

**Mr. Murray**,—Have had it planted for five years; it mildews badly and has not ripened a bunch; do not think it sufficiently hardy for Canada.

**Mr. Arnold**,—Have had it six years in open air, it is a fine grower, is liable to mildew, as indeed do all varieties both native and foreign with me, the fruit scarcely ever ripens.

**Mr. Freed**,—It is more subject to mildew than any other variety, is two weeks later than the Sweet Water, have had it twelve years but cannot get any fruit in the open air.

**Mr. McNab**,—It is too tender, cannot fruit it.

**Mr. Brennan**,—Have had it to bear well three years in succession, it will do in a pet spot, and needs careful cultivation. It is not suitable for Canada generally.

**Mr. Geo. Leslie**,—Have had it six years in a good location but it does not ripen, is very subject to mildew, and not suitable for out door culture.

## DELAWARE.

**Mr. Murray**,—Small bunch and berry, weak grower, abundant bearer, wood very short-jointed and very hardy, one of the finest flavored grapes, ripens about the middle of September or ten days before Isabella.

**Mr. Freed**,—A slow grower and small berry, but fine flavored.

**Mr. Arnold**,—Vine perfectly hardy, a moderate grower, have not yet fruited it.

**Dr. Hurlburt**,—Vine hardy, fruit very high flavored.

**Mr. Holton**,—Hardy, slow grower, have not yet fruited it, but have tasted the fruit raised in Hamilton and found it of fine flavor.

**George Lestie**,—One of the hardiest, have not yet fruited it.

## DIANA.

**Mr. Murray**,—It ripens a week before the Isabella, is a fine grower, hardy, bunch smaller than Isabella, but flavor better.

**Mr. Campbell**,—Have seen it in Woodstock in a very favourable locality, during the last days of September, but it was green, quite unripe.

**Mr. Freed**,—Find it to be a good grower, and am well pleased with it so far.

**Mr. Arnold**,—Produced some fine clusters that had kept very perfectly. It is a favorite with me, one of the best growers, flavor next to the Delaware, berry and bunch larger. It improves on acquaintance, some berries on the bunch ripen before the rest; the average time of ripening ten days earlier than the Isabella; do not think the vine is quite as hardy as the Concord, but is quite as hardy as the Isabella.

**Mr. Holton**,—Have fruited it for two years, and find it perfectly hardy; flavor almost as high as the Delaware; ripens earlier than the Isabella, about at the same time with the Concord.

**Mr. Geo. Leslie**,—Is one of the best yet introduced—a great favorite about Toronto, comes the nearest of any to the Delaware in flavor, and ripens two weeks before the Isabella.

## REBECCA.

**Mr. Murray**,—Is the best hardy white grape, bunch a little larger than the Diana, berries medium size, flavor preferable to the Isabella and equal to the Diana, ripens two weeks before the Isabella.

**Mr. Arnold**,—Is the best hardy white grape, have not yet seen any mildew on this, but expect to, as all varieties seem subject to mildew with me, improves as the vine becomes older, flavor equal to Diana, and it ripens about the same time.

**Mr. Holton**,—I have not fruited it, but find the vine to be perfectly hardy, a moderate grower, and that it ripens its wood early.

## CLINTON.

**Mr. Campbell**,—Have seen it in nearly every county of the Province, it is perfectly hardy, an early and abundant bearer, bunch medium size, berries small, ripens every season, frosts only improve the flavor which is harsh until frost comes, and the fruit keeps well until February.

**Mr. Murray**,—Is perfectly hardy but flavor of second quality.

**Mr. Freed**,—It may be an excellent grape for the North, but not desirable where the finer varieties can be grown.

**Mr. McNab**,—Find it a sure crop every year; by thinning out the berries are very much increased in size, and the flavor is improved by allowing them to hang until frost comes.

**Mr. Alex. Lestie**,—Is hardy and vigorous, and a good fruiter, often ripens irregularly, there being many green berries, flavor second quality, the fruit keeps well.

**Dr. Hurlburt**,—It is very hardy, a good bearer, and the fruit improves in quality by culture.

**Mr. Arnold**,—Is well calculated for the north, perfectly hardy, but not desirable where finer varieties can be successfully grown.

**Mr. Holton**,—It is exceedingly valuable for the north, is the most valuable of any for Canada generally.

**Mr. Geo. Leslie**,—It is the very grape for the northern townships, will yield a good full crop every season where no other crop can be grown.

**Mr. Beadle**,—It keeps the best of any of the grapes so far as my experience goes, retaining its freshness and sprightliness, while the others are heavy and dead.

## ISABELLA.

*Mr. Campbell*.—It sometimes freezes down, can't say that I have seen any ripe in Canada, it colors long before it ripens; it is a free grower and abundant bearer.

*Mr. Murray*.—It ripens in favourable seasons, but is not to be depended on.

*Mr. McNab*.—It is not worth while to trouble with it at Hamilton, some of the seedlings from it ripen about 25th Sept., but they require good cultivation.

*Mr. Alex. Leslie*.—It ripens pretty well at London, but is improved after a little frost, it mildews as bad as any.

*Mr. Arnold*.—It always colors with me, (Paris) but only in one or two seasons have I known it to get ripe.

*Mr. Beadle*.—On the gravelly soil of St. Catherine's it generally ripens, but in less favored positions in my vicinity it very frequently fails to do so.

*Mr. Geo. Leslie*.—It is an old favorite in Toronto, and on the whole is one of the best we have; it ripens if the frosts keep off; shelter and situation are everything; the wood is rather tender.

## CATAWBA.

*Mr. Campbell*.—Has never seen any ripe in Canada.

*Mr. Murray*.—Thinks he saw some ripe this season, but that it is not suited to Canada.

*Mr. McNab*.—Will not often ripen in Canada, except in the extreme south end.

*Mr. Alex. Leslie*.—Does not ripen at London.

*Mr. Arnold*.—Is not worth cultivating, have rarely seen it colored even at Paris.

*Mr. Beadle*.—It ripened in St. Catherine's once in many years, and that only in favourable locations.

*Mr. Geo. Leslie*.—Too late in ripening for Canada generally.

## SWEET WATER.

*Mr. Campbell*.—Is tender, very subject to mildew, not a good bearer, ripens some seasons.

*Mr. Murray*.—Should be planted only in the granery.

*Mr. McNab*.—Have had it 18 years, never ripened more than a few bunches.

*Mr. Alex. Leslie*.—Have tried it for 6 years, but never had any fruit.

*Mr. Freed*.—Had some fine fruit last year, but have seen it mildew badly this same season on older plants.

*Mr. Laing*.—It is too tender for out-doors.

*Mr. Arnold*.—Have not found it more liable to mildew than other varieties, it bears good crops every year with me.

*Mr. Holton*.—It is quite too tender.

*Mr. Beadle*.—Have long ago discarded it as comparatively worthless.

*Mr. Geo. Leslie*.—If kept free of mildew it ripens very well, but it is tender, and requires a good aspect and careful protection.

## NORTHERN MUSCADINE.

*Mr. Arnold*.—It is as hardy as the Clinton, have not yet seen any mildew on it, while other varieties around it were all mildewed, the berry is of good size, though very liable to drop from the bough as soon as it is ripe, bunch small, flavor sweet, very musky, ripens as early as the Isabella.

## HARTFORD PROLIFIC.

*Mr. Murray*.—Is one of the earliest grapes, next to the Delaware in flavor, berry and bunch above medium size, a strong grower, very hardy, ripens about the 1st September; berries are apt to drop from the bunch.

*Mr. Arnold*.—Is the earliest American grape I have, a good grower, hardy, flavor about equal to the Concord or a well ripened Isabella.

*Mr. Holton*.—Have found the vine perfectly hardy, a good grower, have not yet fruited it.

*Mr. Beadle*.—An excellent variety, that promises to ripen well in a large part of Canada, earlier than Concord and nearly, but not quite, equal to it in flavor; perfectly hardy thus far, stood the past winter unharmed when an Isabella by the side of it was cut down to the ground.

*Mr. Geo. Leslie*.—One of the most promising grapes we have, earlier than the Concord and superior to it in flavor.

## PROTECTING GRAPE VINES.

*Mr. Brennan*.—Recommend that all grape vines be covered to protect them from injury by rapid thawing and freezing, use coarse litter from the stable, only a light covering.

*Mr. McNab*.—Uses evergreen branches and corn-stalks.

*Mr. Geo. Leslie*.—A light covering of earth.

*Mr. Freed*.—Would use some clean material, have found material from stable to cause mildew in the wood.

*Dr. Hurlburt*.—Covers with boards.

*Mr. Arnold*.—I use pea straw, covered lightly with earth.

*Mr. Beadle*.—Where snow lasts all winter, merely laying them on the ground so that they will be covered with snow, will be quite sufficient.

On motion of Dr. Hurlburt, seconded by Mr. Freed, it was *Resolved*, that this association recommends that all varieties of the grape be laid down and protected by a light covering during the winter and early spring.

On motion of D. W. Beadle, seconded by Mr. Holton, *Resolved*, That this association recommends the following varieties of grape as giving promise of being better adapted to the climate and soil of Canada than any other with which we are acquainted; viz., Hartford Prolific, Concord, Diana, Delaware and Rebecca.

On motion of W. Holton, seconded by J. A. Campbell, *Resolved*, That this Association recommends the Clinton grape as well adapted for

general cultivation in the colder parts of Canada West—north of Lake Ontario and the Grand Trunk Railway.

The Association then adjourned.

#### SPECIAL MEETING,

Of the Fruit Growers' Association of Upper Canada, held at the City of Hamilton on Thursday February 20, 1862, for the purpose of considering the Report of the Secretary on the answers sent in reply to the questions issued by the Association.

The President being absent, Mr. Holton was called to the Chair.

The Secretary reported that he had prepared an abstract from the answers sent to the association in such a manner as to arrange the information under the head of each county, naming the parties, with their residences, who had responded; that replies had been received from 16 counties, that 26 counties yet remained to be heard from, that of the counties from which replies have been received, very many are from one locality in the county; and suggested the propriety of requesting all the newspapers in the Province disposed to further the interests which this association is designed to promote, to publish the questions issued by the association, and call the attention of their readers to the importance of giving the desired information.

On motion of Mr. Laing, Seconded by Mr. Meston.

**Resolved:** That the abstract prepared by the Secretary remain in his hands until the next regular meeting, and that the Secretary be requested to have the questions published in as many papers throughout the Province as may be willing to insert the same gratuitously.

On motion adjourned.

### The President's Annual Address, delivered before the Fruit Growers' Association of Upper Canada,

By His Honor, Judge LOGIE.

GENTLEMEN,

Before retiring from the office which I have had the honor of filling during the past year, it is my duty to address a few remarks to you, and in the infancy of this society I think I can best advance its interests by directing attention to the objects of the association and its importance not only to the Horticulturist and Fruit grower, but to the general interests of the country, and by stimulating you to increased efforts for the accomplishment of these objects by reminding you of what you have accomplished during the past year, and shewing how successful other societies of a similar nature have been.

The objects then contemplated in the formation of this Society, and which we have been during the past year and are now endeavouring to carry out are,

*First.*—The discussion by members of the Society of the relative merits of the different kinds and varieties of fruit, the determination and selection of the best varieties suitable for cultivation in Canada West, and the publication of the list of fruits so selected and recommended.

*Second.*—The revision from time to time as occasion may require of the Catalogue of fruits, and the addition thereto of such new varieties as may after a sufficient trial be deemed worthy of general cultivation, and striking out the names of any that may on further trial be found unworthy of cultivation, either from being deficient in flavor or not sufficiently hardy to stand the severity of our climate.

*Third.*—The promotion by the society of the cultivation and improvement of native and indigenous fruits, the testing of all new varieties of fruit, the discussion of their merits or defects, and making known the result of such trials.

*Fourth.*—The determination of the names of fruits; and the identification of fruits having different names in different localities, or which, having received new names through the ignorance or fraud of cultivators, have been distributed as new varieties.

*Fifth.*—The discussion of all questions relative to Fruit culture, and disseminating information respecting the same, such as the most proper or most advantageous modes of cultivation, the soils and exposures most suitable for the different kinds of fruit, the manures most beneficial and the best modes of applying the same, the diseases to which the various fruit-bearing trees, shrubs, and plants are liable, with the remedies for such diseases; the insects injurious to the different kinds of fruit, and the best means of preventing or restraining their ravages; the best modes of ripening, gathering, and preserving fruits; and any other subject bearing upon fruit culture.

The importance of these objects is apparent to all who have given their attention to the subject, but the great mass of the people have not given the matter any consideration and are not likely to become aware of the importance to their interests of this Society unless their attention is specially directed to the subject.

No intelligent farmer or intending Fruit-grower would plant an orchard without endeavouring to procure the best varieties suitable to the climate, but with every care on his part he will meet with frequent disappointment (as every one who has engaged in Fruit-culture can testify.) Some of the varieties may turn out to be of inferior quality, for it sometimes happens that a fruit which attains a high degree of perfection in one locality, may prove very inferior in another place where the temperature is a few degrees higher or lower; or a variety of fruit of superior flavor and most desirable for cultivation may prove too delicate to withstand the severity of our climate. To all such as desire to have the *best varieties* of fruit the benefit of such a society as this will be manifest; for, although the dissemi-

nation of information by this Society, respecting the qualities and hardness of fruits, cannot prevent fruit growers from being occasionally disappointed, yet it must be the means of greatly lessening the number of such cases. And if all who have had experience in fruit culture would join the Society and engage in its deliberations much more certain results would be attained, and much greater reliance could be placed upon the list of fruits recommended by the Society.

A large proportion, however, of the farmers of Canada, when they make up their minds to plant an orchard, instead of going to a respectable and responsible nurseryman and obtaining from him *good varieties* of fruit in *good condition*, take from some travelling fruit pedlar or pretended agent for the sale of trees, whatever he may happen to have on hand, and upon his recommendation only. As he has probably bought a stock of trees, and sometimes only the *refuse trees* of a nurseryman's stock solely for the purpose of selling again and *must* sell what he has, whether they are good or bad, suitable or unsuitable to the climate and locality, his interest clearly is to get rid of his trees as fast as possible. The interest of a nurseryman, on the contrary, is to give satisfaction to those who deal with him, as his character and business prospects depend upon his giving such satisfaction. It is not surprising that trees bought in the way I have mentioned from travelling agents and fruit tree pedlars should turn out badly, that a large proportion do not survive, and those which do, turn out to be comparatively worthless; what is surprising is that careful men who would not sow a field with wheat without endeavouring to obtain the best and most suitable kind for seed, or who in raising stock would get the best that their means allow, are careless and indifferent in a matter of such importance as the planting of an orchard. In the event of getting an inferior kind of wheat there is at the worst only the loss of the ground for one year, and if inferior stock is got there will be no loss, as even inferior animals can be sold in a year or two for as much or more than it cost to raise them; but when an orchard is planted with inferior or worthless fruit the case is very different, the use of the ground is in a great measure lost for perhaps 15 or 20 years; how important then is it to secure the best varieties and obtain fruit that will be worth hundreds of dollars annually, instead of having the ground occupied by trees the fruit of which will not pay the expense of gathering and taking to market.

The manner in which fruit trees are bought from tree pedlars and *pretended* agents, and the result of such purchases, is no imaginary case. I have only stated what has again and again been brought under my own notice in the Division Courts in actions brought for the price agreed to be paid for the trees. I trust that this Society and the publication of its proceedings and catalogue of fruits may be the means of preventing

farmers from purchasing trees from irresponsible people, and of inducing them to order the most suitable varieties from reliable nurserymen, or their *duly authorized* agents, who can be depended upon to deliver the kinds ordered in good condition.

As one of the objects of this Society is the naming and identifying of the different kinds and varieties of fruit, those farmers and fruit growers who are not acquainted with the names of the fruits they may have in their orchards, will by joining this Society, and bringing to the meetings specimens of the fruit, get the fruit identified and named by the members of the Society, most of whom are experienced cultivators and well acquainted with all the varieties in common cultivation.

I have to congratulate you upon the progress made by the Society during the past year. During the first year of its existence, owing in a great measure to the lamented death of its first President, the late Judge Campbell, of Niagara, nothing was done towards the accomplishment of the objects of the Society; but during the past year several meetings have been held for the discussion of the merits of the different varieties of fruit and their adaptability to this climate, and a list of fruits has been made and recommended which is complete as far as it goes, it embraces the varieties of apples, pears, currants, strawberries, and raspberries considered most desirable for cultivation in this country; the merits of the New Rochelle or Lawton Blackberry were discussed, and it was decided not to recommend it for cultivation. I hope that during the present sitting the best varieties of the other fruits, such as grapes, plums, cherries, peaches, gooseberries, &c. may be determined, so that before the planting season commences a complete list of all fruits recommended by the Society may be published. I think it is of particular importance that the subject of the best varieties of hardy grape should engage your early attention. A greatly increased interest has for the past few years been felt in the cultivation of the grape in the United States, and that interest is extending to Canada. A large number of the new varieties or varieties with new names are advertised by nurserymen, but little or nothing is known of them; the people generally only know the old varieties, such as the Isabella and Catawba, and perhaps the Sweetwater. And as the object in producing new varieties has been to produce a *hardy grape* that will *ripen early* and produce a fruit of superior quality to these old varieties, it is important to know in how far these objects have been accomplished in any of the new varieties, and to let the public know what varieties have on trial been found to be most desirable for cultivation in this country. In determining the varieties of grape most suitable for cultivation, greater care is perhaps required in coming to a conclusion, than in the case of any other fruit; the quality and flavor of the grape, and its value, particularly

for the manufacture of wine is so dependent upon the quality and nature of the soil, the exposure to the sun, the altitude at which it is grown, and the extremes of temperature to which the plant is subjected, that, as is well known, a vine which in one locality will produce grapes of a particular quality, will not produce them of the same quality in another locality even in the same neighbourhood, hence the necessity of caution in making a selection.

While the progress we have made during the past year should encourage us to persevere in carrying out the objects of the Society, we should also be encouraged to perseverance by remarking the success which has attended similar societies in the United States. In that country fruit growers' Societies have been eminently successful. I shall allude here only to the chief and important one, the American Pomological Society. I believe that society was instituted in 1848 or 1849, and its progress has since that time been most remarkable, its meetings have been attended by fruit growers and those interested in fruit culture from all parts of the United States and California; the discussions, addresses, and lectures have been most successful, and have attracted large audiences. The catalogue of fruits recommended by it have been found most useful and reliable, and it is taken as a standard authority on the qualities of fruit. That Society and others of a similar nature have given an impetus to the cultivation of the best varieties of fruit by diffusing a general taste for the science of Pomology, inspiring fruit growers with greater zeal and industry, and by promoting kindness and good feeling among those interested in the subject.

I have mentioned the importance of a society such as this to individual Fruit growers; it can be shewn to be of equal importance in a national point of view. It was stated by the Honorable Marshall P. Wilder, President of the American Pomological Society some two or three years ago, that it was not more than a quarter of a century since the establishment of the oldest Horticultural Society in the United States, and that the fruit crop of the country was not then deemed worthy of a place in the national statistics. It was also stated, I think, in the same year by Lewis F. Allan, in a lecture on the apple, delivered at New Haven, that after a careful computation he was convinced that the aggregate annual value of the fruit crop of the United States could not be less than \$26,000,000, (twenty six millions of dollars,) that ten counties alone in the State of New York gave an average of \$200,000 each, that Niagara County 25 miles square yielded \$250,000. The fruit crop of the State of New York he estimated as being worth annually \$6,000,000; of New England \$4,000,000; of Ohio \$3,000,000; of Pennsylvania and New Jersey \$3,000,000; of the Northwestern States \$4,000,000; and of the Southern States \$6,000,000. And the value of the fruit crop is constantly and steadily increasing, so great has

been the progress of fruit culture in that country in a few years.

I am not aware that any estimate has been made of the value of the fruit crop in Canada or that we have sufficient data from which to form an estimate. Whatever its value may be it cannot be denied that in Canada the cultivation of fruit has not received the attention which it deserves. While great progress has been made in the science of Agriculture, a progress which is perhaps second to no country in the world, a corresponding progress has not been made in pomological science: much remains yet to be done, and in view of the importance and value of the fruit crop of a country, as shewn by the statistics I have given, we should persevere in the work in which we are engaged, and thereby aid in increasing the resources and wealth of the country. I think we may confidently look forward to a success similar to that attained by the American Pomological Society, and other societies of a similar nature in the United States, and that like important results will follow our efforts.

There is a great pleasure to be derived from the meeting together of those engaged or interested in the prosecution of a scientific enquiry, particularly of any branch of natural science, and the interchange of ideas and opinions on the subject in which they are interested, which those only can fully appreciate who have engaged in such enquiries. And I am sure that all who have attended our meetings during the past year can join me in testifying to the pleasure we have felt in our mutual intercourse and interchange of opinions on a subject so interesting to us all as that of the cultivation of fruit.

In conclusion, I beg leave to express my sense of the honor conferred upon me by placing me in the position of President of your Society during the past year.

### Fruit Growers' Association.

*Series of Questions issued to Horticultural Societies, &c.*

#### THE FRUIT GROWERS' ASSOCIATION OF UPPER CANADA

Desirous to collect and circulate information relative to the production of the several kinds of fruits in the various parts of the Province, respectfully requests the several Horticultural societies, County and Electoral Division Agricultural societies, Township Agricultural societies, and all gentlemen interested in the subject of fruit culture, to cause answers to the following questions to be prepared, and sent to the Secretary, Mr. D. W. Beadle, at St. Catharines, C. W., on or before July 1st, 1862.

As the questions are all numbered, the answers may be numbered to correspond, and thus avoid writing down the question intended to be answered.

## QUESTIONS.

## APPLES.

1. What varieties would you recommend as most suitable to be planted in your locality? 2. What varieties are most profitable for market? 3. What varieties are the most hardy? 4. What varieties have been tried in your neighborhood and found too tender? 5. Are apple trees subject to any disease, or the attacks of any insects in your section, and if so what? 6.

## SEASON FOR TRANSPLANTING.

6 What season has been found most favorable for transplanting, spring or fall?

## DWARF TREES.

7. Have dwarf apple, pear, or cherry, trees, or either of them, been planted in your vicinity, and with what success?

## PEAR.

8. What varieties of pear would you plant in your section? 9. What varieties are most profitable in your locality for growing fruit for market? 10. Have any varieties been planted and found too tender for your climate, and if so what are they? 11. What varieties do you find to be the most hardy? 12. Are pear trees subject to any disease with you, or to the attack of any insect, and if so what?

## PLUMS.

13. What varieties of plums succeed best in your section? 14. Have any varieties been tried which proved too tender for your climate, and if so, which? 15. Which varieties would prove most profitable for growing fruit for market? 16. Is the fruit stung by any insect in your locality, thereby causing the fruit to fall prematurely, and if so what insect? 17. Is the tree liable to any disease, or to the attacks of any insects, and if so what?

## CHERRIES.

18. What varieties of cherries succeed best in your neighborhood. 19. Have any varieties proved too tender to endure your climate, and if so which are they? 20. What varieties can be profitably planted for marketing the fruit? 21. Are the trees subject to any disease, or to the attacks or any insects, and if so, what?

## PEACHES.

22. Can the peach tree be grown in your section, and if so, what varieties succeed the best.

## APRICOTS AND NECTARINES.

23. Can the apricot or nectarine, be grown in your section, and if so what varieties succeed the best?

## QUINCE.

24. Can the quince be grown successfully in your section?

## STRAWBERRIES.

25. What varieties of strawberry have been

found to succeed well in your neighbourhood? 26. What varieties would you plant for market?

## RASPBERRIES.

27. What varieties of raspberries have been found to succeed best in your locality? 28. What varieties do you recommend to plant in your neighborhood, for growing fruit for market?

## GOOSEBERRIES.

29. What varieties of gooseberries succeed best in your section? 30. Is the fruit ever covered with mildew? 31. Do you know any varieties that are exempt from mildew in your section? 32. Do you know any means of preventing the mildew, and if so, what?

## BLACKBERRIES.

33. Has the New Rochelle blackberry been tried in your vicinity, and with what success?

## CURRANTS.

34. What varieties of red, white, and black currants are most esteemed in your locality?

## GRAPES.

35. What varieties of grape have been planted in your section? 36. Have any of them proved altogether too tender for your climate, and if so, which? 37. Have any of them proved perfectly hardy, and if so, which? 38. Do any of them invariably ripen their fruit well every season, and if so, which? 39. Are there any vineyards planted in your neighbourhood, and if so with what varieties? 40. Any other information, pertinent to the subject, such as the character of the soil that predominates in the orchards of your section; the soil found to be most suitable to the several kinds of fruit, &c.

41. Do you know of any seedling fruit of merit in your vicinity? if so please give its history and description: kind, size, color, quality, time of ripening, growth of tree, &c., &c.

Editors of papers throughout the Province are requested to give the above one or two insertions, in order that there may be every opportunity afforded to make the information sought, as full as possible.

## The Culture of Asparagus.

Read by Mr. H. Shaw, Gardener to R. Juson, Esq., before the Hamilton Horticultural Club.

Mr. PRESIDENT and GENTLEMEN.—In attempting to write a few remarks on the culture and management of Asparagus, it is not required that I should go on to speak of the history of this vegetable. It is found a native plant on the sea shores of Britain. Asparagus has a perennial root and annual stalks, it has two varieties, the purple and the green. The purple is a larger kind, growing fuller and closer; although handsomer in appearance, it is not considered so good in flavour as the green. But to discuss varieties and their

is not my object here, but rather to give a few practical hints on the formation of an asparagus bed, and its management afterwards.

The first point is the selection of a suitable spot of ground. The asparagus likes deep sandy loam, and the ground should, at least, be trenched two and a half feet deep, laying in the bottom about eight inches of solid cow manure. Care should be taken that the whole of the ground is turned regularly, and no ribs left behind the trenches. When the required space is turned up in this manner lay on a good covering of well decomposed manure, taking care to keep the surface level as you proceed.

After the ground is thus prepared the next step is procure one or two year old plants from the seed; two year old plants are preferable because they will give asparagus one season earlier for table. The period at which all has been got ready, ought not to be later than the second week in April, if spring planting is preferred, and last week in October for fall planting. I have sowed asparagus seed in the first week in May in Canada, and planted the following October upon ground prepared as stated above, and in a part of Canada more rigorous in climate than my present locality, and I cut very fine asparagus from it the third year, fit for any table; but by planting two years old plants it can be used the second year after planting. Now as to planting the ground so prepared.

Asparagus is generally plowed in beds about four feet wide, thus giving three rows to the bed at eighteen inches from row to row, the side rows being six inches from the edge of the bed, and in the row fifteen inches from plant to plant. But no benefit is derived from close planting. I believe two feet from row to row and eighteen inches from plant to plant is preferable and will yield finer asparagus. In planting, the crowns should not be more than one and a half inches under the surface for the covering every season adds to the depth over the crown. The beds should always be kept free of weeds, and the surface kept loose and free, which greatly tends to the vigorous and healthy growth of the plants. This should be attended to throughout the whole season of its growth, more especially the first season after planting, and in the fall, when the stalks are fully ripe, and cut off, the bed or beds should be covered two or three inches thick with good rotten manure, and over all a covering of stable dung or some litter as a protection against frost. This is the finishing touch for the fall. In the spring the litter should be removed, and a good sowing of salt given regularly over the bed, and then a three pronged fork used to loosed the surface and mix all the short manure left on the bed. The alleys also should be forked up, throwing a little sprinkling

over the bed, which should afterwards be neatly raked.

Asparagus beds so prepared and attended to will last a quarter of a century. I have seen at Airthrey Castle, Stirlingshire, Scotland, asparagus beds which had been cut for a period of fifteen years, and looked as if they would stand other-ten years. I believe it the best maxim that whatsoever a man doth, let him do it well." It gives most satisfaction and rewards the individuals at the end. I think every person who has a few square yards of spare ground ought to have his asparagus bed, all the trouble and expense is the formation of his bed; after planting there is but little trouble and expense attending it. And amongst all the vegetables there is none more relished than the asparagus coming in use early in the season, when there is very little else can be had from open air growth. It is always furnished for the table of the rich, but it is also within the reach of the poor man who can commend a small patch of ground that he can call his own.

#### *For the Canadian Agriculturist.*

#### **Dwarf Apple Trees Again.**

I was just about to comply with the request made in last year's *Agriculturist* by Mr. Beadle, to say a few words about dwarf apple trees, when I received your last number, containing some rather severe, and, I think, unwarrantable strictures, from R. B. Werden, upon "the representations made by the nurserymen in their catalogues and books, that the dwarf apple will bear when it is a small bush, or like the dwarf pears." This Mr. W. pronounces "only a humbug, and done for the purpose of selling their trees." Many persons will no doubt look upon such a charge as calculated to excite the displeasure of all nurserymen, who have ventured to say a word in favour of the early bearing properties of the dwarf apple. But I am very much inclined to think that every Canadian nurserymen can afford to smile, and to impute Mr. Werden's disappointment in his dwarf trees to his former unsuspecting credulity, or to his ignorance of the requirements of the trees so bitterly complained of. "For the purpose of selling their trees" indeed! Now if Mr. W. knows this to be a fact, he perhaps can tell us of some nurseryman who has a surplus of genuine dwarf apple trees, upon the true paradise stock. I have never yet known such, and should be much obliged for the information, having long been under the impression that the demand was greater than the supply.

Now sir, I shall venture to predict, that the barrenness of Mr. Werden's trees is traceable to one or more of the following causes, viz., to having been grafted several inches below the surface of the soil, and that they are now principally growing upon their own roots, instead of

depending solely upon the roots of the paradise stock; or they have not been grafted upon the paradise stock at all; perhaps they may have been grafted upon the Danem stock, or upon seedlings from the paradise apple, a large portion of which will, in all probability, partake more of the character of the apple trees fruiting at the time in their immediate vicinity than of the original paradise.

Mr. Werden concludes his remarks by asking "for more information respecting dwarf apple trees," which leaves the impression upon the minds of his readers, that he was losing confidence, either in his "most responsible nurserymen in Rochester," or in himself as a skillful cultivator. Now, Sir, if my opinion and experience were asked in this matter I should say more in favor of the early bearing properties of dwarf apple trees than Mr. Werden accuses those "humbug nurserymen" of saying, viz., that they will, when properly managed, fruit earlier than the dwarf pear.

Let us suppose, Mr. Editor, that you are about to plant 12 dwarf apple trees, say of the following varieties, Red Astrachan, Melon, Baldwin, Sweet Bough, Summer Rose, Golden Sweet, Wagner, Northern Spy, Benoni, Early Strawberry, Gravenstein, Keswick Codlin, and when got from the nursery they will be only two years from the bud perhaps, and, if good, they will be little stunted looking things, from one foot six inches to two feet high, budded at the ground, and when transplanted, let the bud be two inches below the surface. Some varieties, such as Northern Spy, will need shortening in to encourage lateral growth, and pruned a little every year to keep the head open and encourage fruit spurs. Other varieties, such as Wagner, will need no other pruning than picking some of the young fruit, and encouraging the growth of wood; let the strong growers be put on rather poor soil, and the tardy growers upon good soil, and all kept free from the bark house, and I am satisfied that every person who wishes to combine in one small tree or bush all that is useful, healthful, and beautiful, in flower and fruit, will find nothing approximate so near to his desires as the dwarf apple tree.

Now, Mr. Editor, let me invite Mr. Werden to visit the town of Paris, any time between the months of June and November, and if there are any apples in this part of Canada, I think he may see some here, on bushes not more than three or four years old, and from two to four feet high. We will also show him some of these bushes, after being planted ten years, that have now heads from 20 to 35 feet in circumference, and have borne at least seven good crops of apples.

Hoping that Mr. Werden will endeavour to examine his dwarf apple trees, ascertain the cause of their unfruitfulness, and report the same to the *Agriculturist*, I remain yours, &c.,

CHARLES ARNOLD, *Nurseryman*.

Paris, C. W. February 17th, 1862.

## Peterborough Horticultural Society.

In a recent number of the *Peterborough Review* we find a report of the Annual Meeting of this new Horticultural Society, at which the following remarks, showing the progress of the Society, were made by the able President, the Rev. V. Clementi.

Gentlemen,—This being the first annual meeting of the Peterborough Horticultural Society, permit me, ere we proceed to the election of the officers for the ensuing year, to address a few words to you, relative to the proceedings of the society during the season which, according to our By-law, has this day expired.

On Tuesday, the 9th day of April, last year, a few members of our community, actuated by a feeling of the advantages derivable from the establishment of a Society devoted to the encouragement of a more careful cultivation of flowers, and fruit, and vegetables, in the town and its vicinity, convened a meeting for that purpose, at which it was arranged that a general assemblage of such as were disposed to assist in the formation of an Horticultural Society, should be summoned for the 16th of the same month. Adverse circumstances preventing a large attendance on that day, the meeting was further adjourned to the 22nd, on which day a Constitution and By-Laws were adopted, and officers appointed for the current twelve-month.

It was at first intended that there should be two Exhibitions during the year; the season, however, proving unpropitious, and other matters of great local interest intervening, the spring Show was abandoned, and the only exhibition on which we ventured took place, in the Town Hall, kindly, and without hesitation, placed by his worship, the Mayor, Chas. Perry, Esq., at the disposal of the Society, on the 4th of October: an exhibition that, but for the exceedingly unfavourable state of the weather, would have proved successful almost beyond the hopes entertained by the most sanguine.

Such, gentlemen, irrespective of the detailed reports of the Secretary and Treasurer, is a brief statement of our transactions during the past season.

Before I resume my seat, however, allow me to inform you that, having accidentally met with a notice in the *Leader*, of a meeting intended to be held in Toronto, on the 30th of last month, composed of delegates from the various Agricultural and Horticultural Societies of Canada West, I made a point of attending that meeting; and I can assure you that the upper section of the province was most fully and ably represented, Colone Thomson occupying the chair.

The object of the meeting was to frame a new Bill to be brought before the House of Assembly during the coming Session.

I will not trouble you on this occasion, with

any remarks referring to the Agricultural portion of the Bill. Mr. John Walton, President of the Peterboro' Agricultural Society, was also present, and was satisfied that the interests of the community he represented were amply secured. Suffice it to say that after an hour's adjournment (we sat from noon till mid-night); at 7 o'clock the Hon. Mr. Allan moved that the following clause be embodied in the Bill, and that the motion was carried:

"Every Horticultural Society in any city, town, or incorporated village, incorporated under this act, or which may have been incorporated under any other act of the Provincial Legislature, shall be entitled to a public grant equal to the amount subscribed by the members of such Society, and certified by their treasurer to have been paid into his hands in the manner provided by the sections of the act relating to Agricultural Societies, provided that the whole amount granted to any such Society, shall not exceed one hundred pounds in any year."

I did myself the honour to address the meeting in advocacy of the claims of the Horticultural Societies. The fact of the Reporters not having returned "from refreshment to labour," until after Mr. Allen and myself had spoken, may account for no mention being made in the newspapers of our remarks.

If the Bill passes the Houses, and I entertain no doubt at all upon the subject, the Horticultural Societies will be placed in a similar position to that occupied by the Agricultural Societies.

A certain number of members will be required, and a certain amount of subscription; and then that amount will be met by an equal sum from the Government. The number is not to be less than 25; and the gross amount must not fall short of \$40.

### Report on Fruits.

The Transactions of the Massachusetts Horticultural Society for the year 1861, comprise a valuable report, submitted by J. S. Cabot, Esq., Chairman of the standing Committee on Fruits.

Having taken a view of the meteorological phenomena which characterized the past year, and noticed the injury which fruit trees sustained, the report refers to the important fact that some varieties of the same species suffered much more than others—a fact which is calculated to impress upon the minds of cultivators, the necessity of adopting the most hardy kinds. Thus speaking of pears, the report says:

"The Bartlett and Beurre Bosc suffered greatly, the trees of both having been almost universally severely injured, and in most instances wholly killed; while on the contrary, the Marie Louise, Belle Lucrative, the Urbaniste and Louise Bonne de Jersey, seemed to escape wholly unharmed; the two first of these last-

named having been, the past season, superior in quantity and quality to any season now remembered."

In regard to the special causes of the great destruction of fruit trees, the report states that perhaps no perfectly satisfactory conclusion can yet be reached, but makes the following suggestions:—

"If the attention of fruit growers should be drawn to a consideration of the matter, and by collecting of facts and comparing of opinions, some definite conclusion, as it might be, should be reached, it might induce a mode of cultivation that should measurably guard against a recurrence of the evil. On a previous occasion, similar to that of the present, the opinion was expressed that shelter to some extent, to be obtained either in the selection of a site or by artificial means, was an important element to success in the cultivation of some varieties of fruits, if not absolutely essential thereto; and this opinion has been strengthened and confirmed by observation the past season, when injury has been almost universal, and exemption from it the exception, it has been noticed that gardens or orchards that were in some way sheltered, have almost wholly escaped injury."

In this connection reference is made to the means of protection, and it is said:—

"This may be obtained by selecting a sheltered site for the garden or orchard; and where that cannot be done, by the erection of a high, close fence around it. If any question arises as to the efficacy of this last method, it needs to dispel the doubt, but a visit to the garden of Mr. Tudor, at Nahant, where, protected only by a high paling, fruit trees of all varieties may be seen flourishing luxuriantly, while outside of such enclosure, the hardiest trees cannot resist the influence of the fierce winds that blow over the peninsula. And there is no ostensible cause for the exemption from injury of the trees of Mr. Bacon of Roxbury, and Mr. Vandine, of Cambridge, and that these bore full crops of fine pears in a year so unpropitious as the past, but the shelter they receive. It further inculcates the importance, or the necessity, where profit is the object of culture, in a choice of varieties, of selecting the most hardy, keeping to view the quality of the fruit. There seems to be as much difference in the vigor and hardihood of different varieties of trees of the same species, as in the different races of animals of the same species; and it is only upon the more vigorous and hardy that a reliance can be placed."

Of strawberries, the new kinds are spoken of which were exhibited at the shows of the Society by Messrs. Hovey, and which we noticed at the time, and as we saw them on Messrs. H.'s grounds. The La Constante is described as "a magnificent fruit, of great size and beauty, of a fine color and good quality." Scott's new seedling, Lady of the Lake, is favorably mentioned. The practice of

the Belmont cultivators is alluded to as "entitled to great consideration." They depend mainly on "Hovey's Seedling, with the Jenny Lind, Boston Pine, or Brighton Pine as a fertilizer; planting them in the proportion of about six of the former to one of the latter, and setting them to single rows about four feet apart, and taking but one crop from the same vines, have new beds every year."

In regard to currants, the last year is said to have been the only one remembered in a period of forty years, in which this fruit has been much injured. Last year the blossom buds were in a great measure destroyed. Of new varieties, the La Versailles and Dana's Transparent are mentioned. The former is considered in Europe one of the best, if not the best, grown. The latter is described as very large, of fine flavor, and represented to be a great bearer.

Of raspberries, nothing particularly new was brought out last season. The Catawissa, which was exhibited as late as October 18th, may be deserving of cultivation where it is desired to prolong the season of this fruit.

Blackberries suffered severely last year by the destruction of the vines, and small quantities only were exhibited.

Of cherries, a single one from Randolph, and a branch with half a dozen black mazzards from Newburyport, were the only specimens of this fruit, grown in the open air, exhibited last season. The crop may be said to have been entirely destroyed. It is thought that many trees will not entirely recover from the effects of the winter of 1860-1.

Of peaches, there were none the past year, and the trees suffered severely—old ones being nearly all killed.

Pears, although the crop was much below an average, were generally of fine quality, owing in a great degree to the favorable autumn, and some varieties, as before mentioned, produced tolerably well.

Grapes, where the vines were wholly exposed, even in favorable situations, were much injured by the winter. Some varieties were less injured than others, among which are mentioned the Delaware and Hartford Prolific. Out of a collection of some eight or nine varieties, those and the Clinton are said to have been all that escaped serious harm. But the past summer and autumn are said to have been the most favorable for grapes of any remembered.

Some varieties, which seldom ripen here in the open air, as the Isabella, reached full maturity. Of hardy out-door varieties, E. A. Brackett exhibited a seedling, described as a black grape, heavy bloom, large bunches, thin skin, little or no pulp, very juicy, sweet and very vinous, stated by Mr. B. to have been ripe on the 10th of September. The Committee regard it as the most promising

new grape that has been brought to their notice. The hybrids of E. S. Rogers, of which we have spoken several times, are noticed, particularly No. 4 and No. 15. In regard to the experiments of Mr. Rogers and others, it is said:—

"Considered as a purely scientific experiment, that of Mr. Rogers must be deemed an eminent success; his seedlings of the first generation have parted with much of the distinctive character of the native variety, and and show plain traces of their foreign parentage. Whether he has met with equal success in originating varieties that shall, from early ripening and hardiness, be suited to the general wants, is yet to be established. . . . Although Dr. Van Mons has taught, and apparently established, a contrary theory—that of improving varieties by raising successive generations of seedlings—and that it may be thought presumptuous to call in question the teachings in Pomology from such a source, yet some doubt cannot but be entertained that hybridization is in the pursuit of this object, viz., the production of improved varieties, essential to success, and the raising of successive generations of seedling grapes from a native or wild variety under circumstances where admixture of other sorts was impossible, might be pursued not for eleven generations—when according to Van Mons, all the seedlings would be good, when the naming of varieties would become unnecessary, and propagation by grafting and budding cease—but for double that number, without showing any very marked improvement."—*Boston Cultivator*.

## Veterinary.

### Inflammation in Animals.

[Lecture by Professor Dick, Principal of the Veterinary College, Edinburgh.]

In this lecture it is proposed to give a short account of the inflammatory process, more particularly with reference to its nature. Owing to the frequent occurrence of inflammation, and the serious consequences with which it is often attended, it has from the earliest time demanded, and still demands, a great deal of attention; indeed, the greater part of medical and veterinary practice consists in the treatment of some form of inflammation, so that it is obviously of the utmost importance to have as clear ideas as possible with regard to its nature. Unfortunately, however, the subject is surrounded with many difficulties, and the vital powers of the animal body on which the phenomena of inflammation depend are so peculiar and complex

in their action, that up to comparatively recent date little was known of it as of satisfactory character. Previous to the employment of the microscope as a means of research, our knowledge of the inflammatory process was of the crudest kind; and even at this time, notwithstanding the labours of many observers, it cannot be said that the subject is by any means exhausted. Much, however, has been done in the present century to elucidate this subject, and we are now possessed of information which will enable us to follow with a considerable degree of accuracy the complex phenomena which constitute inflammation. And here, at the outset, it may be observed that there is nothing peculiar in the inflammatory process apart from the ordinary operations going on in the body. Inflammation is a vital process in the same sense as the secretion of bile or of urine is a vital process. As we shall see further on, inflammation of a part is dependant on the operation, not of foreign and extraneous forces, but of the ordinary and innate vital powers. If therefore, we knew the *modus operandi* of the vital powers in the ordinary or healthy functions of a part, we would also know the manner in which the vital forces act in inflammation. It is owing to this circumstance, viz., that the forces at work in a state of health are the same as those in a state of disease, that physiology and pathology are closely connected and mutually illustrative of each other. Indeed, properly speaking, there is no such science as pathology; it should rather be called pathological physiology. The difference, therefore, between a morbid and a healthy process is one not of a kind, but of degree. There are some processes, however, called morbid, which considered in themselves are perfectly healthy, but are regarded as morbid, because they take place at an improper place.

As health and disease are merely modifications of the same state, and pass gradually into each other, it is impossible to draw a sharp boundary line between them; for this reason a strictly scientific definition of health or disease cannot be given. For practical purposes, however, a part may be said to be diseased when the processes going on in its interior either endanger its structure or jeopardise the life of the whole organism.

In order to arrive at a knowledge of the phenomena of inflammation, it will be necessary to examine with the microscope the web of the frog's foot, both in its healthy condition and when irritated in various ways. If you place the web of a living frog under a microscope which magnifies 250 or 300 diameters, and bring one of the arteries into the focus of the instrument, you will observe the blood rushing along so rapidly that it is impossible to distinguish any of its constituents. If,

however, you follow the artery, it will be found to break up into numerous small vessels of uniform size, in which the current of the blood is instantly diminished to such a degree that you can readily see the constituents of that fluid. The combined calibre of the capillaries in which an artery terminates is considered greater than that of the artery itself, and consequently the rapidity of the current is immediately diminished in accordance with the well-known hydrostatic law, that the rapidity of the current diminishes in proportion to the width of the stream. Even in capillaries, however, the rapidity of the current stream is considerable. The corpuscles pass with great facility through the vessels, and do not exhibit any tendency to adhere to each other, or to the wall of the vessels. This is true both of the red and colourless corpuscles. It is usually stated that the colourless corpuscles move sluggishly along the *still layer*, as it is called, or the fluid portion of the blood, which is in contact with the walls of the capillaries. This is not the case, and, as already mentioned, the colourless corpuscles pass along as rapidly as the others. With regard to the terminal arteries, they are almost entirely composed of muscular fibres. These fibres belong to the plain or unstriped variety. They are arranged in one or more layers, according to the size of the artery, either circularly or in a spiral manner round the vessel. When they contract, therefore, they have the power to diminish the calibre of the vessel, or, if the contraction be strong enough, to occlude it completely. In this way the small arteries are able to regulate the supply of blood to a part. In addition to their contractile properties, arteries are also endowed with elasticity. Under ordinary circumstances, the arteries possess a certain medium size; but when, as sometimes happens, the restraining influence of the muscular fibre is removed, the vessels enlarge from the distending force of the blood, so that a much larger quantity than usual of blood finds its way into the part at the same time, owing to the unrestrained flow of blood. The capillaries beyond enlarge, and the velocity of the current is increased. When the muscular fibres again contract, the artery resumes its original size. The amount which passes through the artery, as well as its velocity, is diminished, and if the contraction proceed far enough, so as to occlude the vessel, the circulation through the artery will be stopped altogether. With regard to the capillaries of the numerous small vessels in which the arteries terminate, they are composed of a thin homogeneous membrane, in which nuclei of a flattened form are embedded at intervals. They are possessed of considerable elasticity; but, unlike the arteries, are completely destitute of contractility. Any alteration in size of the capillaries

which may take place is not due to any vital property possessed by these vessels, but is simply owing to the greater or less pressure exerted by the blood upon their walls. As already remarked, the blood flows rapidly through the vessels, much more rapidly through the arteries than through the capillaries, the blood corpuscles, both red and white, showing no tendency to adhere to each, or to the walls of the vessels. At the same time the current is equable and not pulsatory or jerking, as might have been expected from the rhythmical action of the heart.

If now the web be gently irritated, the artery immediately contracts at the point irritated, the calibre of the artery being either diminished or completely obliterated, and the circulation is either impeded or brought to a stand still. This condition, however, is soon followed by dilatation—excessive dilatation of the artery; and the blood rushes through in larger quantities, and with greater rapidity than usual; and in consequence of this unrestrained flow of blood through the artery, the capillaries beyond likewise become distended and gorged with blood. In this state the circulation through the vessels, both artery and capillaries, is more rapid than in the normal condition; but the blood corpuscles do not present any deviation from the healthy standard. But now the artery begins to contract and to resume its usual size, and when this takes place the circulation presents the same appearance as it did prior to the experiment. This experiment may be repeated several times in the same part with the same result. Here it is obvious that we have no inflammatory phenomena before us. The irritation has merely been sufficient to excite the artery to contraction, and this contraction was followed by complete relaxation or inactivity of the muscular constituents of the artery, in accordance with the general law in physiology, viz., that when a part has been called into vigorous exercise it loses after a time its functional activity, and does not regain it until a period has elapsed proportionate to the degree of its previous activity. If now the web be irritated more strongly, additional phenomena ensue, which we recognise as inflammatory. The arteries dilate immediately, or at most contract spasmodically for an instance and then dilate much beyond their usual size. The blood then rushes on in larger quantities and with greater speed, and gorges the capillaries, as described above. Soon, however, the circulation becomes slower and slower, until it becomes much more languid than the normal circulation. It then oscillates, and at last comes to a complete stand-still. Meanwhile the arteries, as well as the capillaries, are fully distended, and apparently offer no obstacle to the free passage of the blood. It is evident, therefore, that the vessels have no

special influence in causing the stoppage of the circulation in a part about to become the seat of inflammation. On examining the blood itself, we find that the corpuscles exhibit a remarkable tendency to adhere to each other, as well as the walls of the vessels. In the healthy state, as already remarked, the corpuscles have no tendency to adhere to each other or to the vessels, and there is therefore, little doubt that the viscosity of the corpuscles in the inflamed part is the immediate cause of the stoppage of the circulation. While circulation is stagnant in the inflamed part more is constantly arriving, being propelled forward by the action of the heart, and, in consequence, the capillaries soon become enormously distended with blood corpuscles. Usually the capillaries are distended irregularly, so as to form pouches or sinuities, and sometimes owing to the greater pressure exerted upon them, they burst, and allow the blood to become extravasated into the tissue. While the varicose condition of the capillaries is the immediate cause of the stoppage of the circulation, it may be asked what is the cause of this condition of the corpuscles in the inflamed part? The corpuscles before they come to the inflamed part, are quite normal; when they arrive there they become viscid, and when they leave it they resume their normal appearance. The cause of the viscosity, therefore, cannot be due to any primary alteration in the blood; if it were so the viscosity of the corpuscles would remain after they had left the part. Accordingly, we are forced to look elsewhere for the cause, and we shall probably find it in the textures themselves.

(To be continued.)

---

## Miscellaneous.

---

### The Welsh Pony.

The pure Welsh pony, to which the palm over other ponies has been yielded over and over again at the West of England Society's shows, has been celebrated from all time. To be born of a Welsh mountain mare I hold to be as high a lineage as can befall a horse. A relic are they probably of the gallant sort which Cæsar describes as tearing through the ranks of war in the scythed chariots of his British foe, pawing terribly in the valley (as is so magnificently pictured the Arabian in the oldest book on record) snuffing the battle afar off, the thunder of the captains, and the shouting, so that it required all his personal influence besides his presence to induce his tried troops at length to recover from their consternation; the trained docility and sure-footedness of which astounded him, as they

were reined up, he tells us, at full stretch in the most steep and difficult places; a number of which were subsequently thought worthy of being transported to Rome with a view to the improvement of the Italian horse, and became a favourite breed with the aristocracy of the day; so that their likeness very probably suggested to the eye and mind of Virgil that graphic description of a noble animal that he has left us in the Georgics. From this time forward, "occasional mention is made of the excellence of British horses. The Saxons appear to have paid great attention to the horse, and to have been fully aware of the importance of improving the breed. The cognisance which waved on the Kentish royal banner was a white horse. Of what character were the native breeds up to the Norman Conquest it is now impossible even to guess. That they were powerful and well suited to the purposes of war, both by their stature and training, we have the testimony of Cæsar before mentioned, and of subsequent historians; but the first attempt on record to improve the native stock by the introduction of foreign blood, occurred during the reign of William the Conqueror, when Roger de Belesme, Earl of Shrewsbury, imported the elegant and docile Spanish horse, and bred from it on his estates in Powis land; and it is recorded that the horses of that part of Wales were long celebrated for their swiftness—a quality which they doubtless derived from this happy mixture of blood."—(Yarrell.) At a subsequent period there is a tradition of some foreign horses swimming ashore from a wreck in the British Channel, and escaping clear to the hills. Of recent years great occasional efforts have been made by various landed proprietors in North and South Wales to improve the breed by turning out occasionally an Arab; but the small farmers on the mountain-side stand greatly in their own light, and persist in neglecting material which in skilful hands might prove a very mine, and which, even as it is, yields occasionally most exquisite specimens. To see a herd in summer-time beneath you in the hollow of the Black Mountains gathered by a spring—of all ages, yearlings, foals, colts, two-year-olds, with the brood mares white from age—and then to contemplate the ragged-jointed indescribable that is lord of the troop, it is a wonder that anything tolerable ever passes to the lowlands. But it is about Christmas time, that, as a purchaser, you have a chance of selecting deliberately to suit your taste. Then when the Siberian weather sets about those everlasting hills, and by the

"Precipices huge  
Smoothed up by snow"

there is no longer any picking to be found, they descend to the boundary of the common land, and are admitted into strawyards, being all distinguished by their respective owners through special marks upon the ear or flank. Then is

there opportunity for a judge to pick many a valuable colt from amidst the bright-eyed bears (for they look like nothing else), as they crowd nervously into a corner on your approach, ready to spring over if it be not exceeding high, or cat-like scramble across in a moment. Some five-and-twenty years ago, the noble-hearted proprietor of Rug, in Denbighshire, Colonel Vaughan, lineal descendant of Prince Llewelyn, took great pride in the improvement of a tribe upon the neighbouring Berwyn range. The picture of his Apricot I have beside me as I write, 12½ hands in height—a bright chesnut, with a beautiful small head, full eye, elegantly turned quarters, muscular thigh, arch neck, and a Blink Bonny shoulder, the victor of a hundred races at Ruthin, Mold, and on the historic flats of Harlech, against much taller horses than himself more than once. I am glad to know that there is a good sprinkling of his stock left yet in Merionetshire. How those whipper-in lads attached to the Rug fox-hounds would on their ponies overtop the highest wattled fence, creep in and out of the ugliest thicket, stream down the steepest hill-side without halt or blunder, then rein them at the bottom as cool as any travelled hunter, so calmly to trot off with a message for the master.—*Beever's Notes on Fields and Cattle.*

**PERSEVERANCE**—At the close of the last century, a poor, awkward, uncouth boy entered London; but he was so long, lank, and ungainly, that he seemed fit only to be the drudge of a printing-office—run errands, bring water, sweep the floor, and the like. Already had poverty and the hardness of the world made him sour, unhopeful, and despondent. Under less discouragements, many a youth has abandoned himself to a thriftless life, having no higher aim than to live but for the day; or, worse still, has plunged headlong into all the extravagances and indulgences connected with thriftlessness and crime. But the boy had vigorous health: this imparted to him a mental *vim* a moral power, which soon showed itself to his employer. He was prompt, persevering, and painstaking; and with these three qualities, in spite of the fact that he was good at nothing (in everything tolerably only), he made his patient way, step by step, to the "woolsack," (that is, the seat of the highest judge in England), and lately died worth £200,000 among the most honoured men of his nation and age, Lord Chief Justice Campbell. In this case, vigorous health was a mine of wealth, a better fortune than if he had been the heir of many thousands. And certain is it, that the world would be a happier world, and the men in it would be happier, better, and greater, if one time of the time, and care, and study, which parents bestow on the accumulation of money to leave to their children, were devoted to the physical education and training necessary to secure

a vigorous constitution. Of any two young men starting on the race of life, one poor but healthy, and the other rich and effeminate, other things being equal, the chances for usefulness, honour, and a well-remembered name, are manifold, in favour of the former. Every man of the least observation and reflection knows this to be an indisputable truth. Yet, in view of the fact that vigorous health is a better and safer fortune than stocks and bonds, how many in each hundred parents who read this article will lay it down and resolve: "I will do more to leave to my children a vigorous constitution?" Another element in the success of Lord Chief Justice Campbell was, that his employer, seeing his dull nature, but noticing at the same time that when he had anything to do, he went at it promptly, and, with great painstaking, kept at it until the work was done, although painfully slow, he patted him on the shoulder, always spoke cheerfully to him, and, with considerate consistency, threw little jobs in the way, by which the heavy boy might earn a little money, and be stimulated to greater activities. How many a youth at school, how many an apprentice in the shop, how many a child in the family, has gone out in the night of a blighted life, who with humane encouragement, might have lived usefully and died famous, let the passionate teacher, master, and parent inquire, and do a little more patting on the shoulder!—*Hall's Journal of Health*.—

**THE TYRANT FLYCATCHER**—This bird is one of the migratory visitors of the United States, and often bears the name of "King," as well as "Tyrant." According to Wilson, he does so from the extraordinary authority he assumes over all others during the time of breeding. So great is his affection for his mate, his young, and his nest, that, suspicious of every bird that approaches it, he violently attacks all intruders. In the month of May, June, and part of July, his life is one continued scenes of broils and battles, in which, however, he generally comes off conqueror. Strange to tell, hawks and crows, the bald eagle, and the great black eagle, all equally dread an encounter with him, who, as soon as he perceives any one of them approaching, launches into the air, mounts to a considerable height above him, darts down on his back, and sometimes fixes himself there, to the great annoyance of the assailed, who, if no convenient retreat or resting-place be near, strives, by various evolutions, to free himself from his merciless adversary. But the king-bird is not easily dismounted. He teases the eagle incessantly, sweeps upon him from right to left, rises, that he may descend on his back with greater violence, all the while keeping up a shrill and rapid twittering, and continuing the attack, sometimes for more than a mile, till he is relieved by some other of his tribe equally eager for the fray.—*Cassell's Popular Natural History*.

**ALL HAVE INFLUENCE.**—No man stands alone in the world, but is influencing, for good or evil, many of his fellow-creatures. "What can I do?" is an oft-repeated question, especially among those who fancy they are so low in the social scale, or so poor in ability that their example can have no effect. "Billy Dawson," the well-known Wesleyan preacher, was once preaching on "Influence," and at the close of his discourse, a farmer said to him, "Your remarks are very good, Mr. Dawson, but they scarcely seem to apply to me. I have no more influence than a farthing rushlight." "A farthing rushlight!" said the preacher, "why, a farthing rushlight may set fire to a haystack, afford a poor woman the light to read a chapter in her Bible; or, placed in the window of a cottage on a desolate moor, may guide the weary, footsore, and lost traveller to a place of rest and safety." And so it is with the moral world. A kindly action, a word in season may effect a great change in the character of a man; and, just as a small stone is capable of turning out of its course the current of a stream; so the influence of the weakest of God's creatures may often effect the greatest of good. It should be remembered that because the man had but one talent, it was no excuse for him when it was discovered that he had buried it in a napkin.—*Old Jonathan*.

**FLORENCE NIGHTINGALE ON CRINOLINE.**—It is I think, alarming, peculiarly at this time, when the female ink-bottles are perpetually impressing us "woman's particular worth and general missionariness," to see that the dress of women is daily more and more unfitting them for any "mission" or usefulness at all. It is equally unfitting for all poetic and all domestic purposes. A man is now a more handy and far less objectionable being in a sick room than a woman. Compelled by her dress, every woman now either shuffles or waddles; only a man can cross the floor of a sick room without shaking it.—What is become of woman's light step—the firm, light, quick step we have been asking for? A nurse who rustles (I am speaking of nurses professional and unprofessional) is the horror of a patient, though perhaps he does not know why. The fidget of silk and crinoline, the rattling of keys, the creaking of stays and shoes, will do a patient more harm than all the medicines in the world will do him good. The noiseless step of woman, the noiseless drapery of woman, are mere figures of speech in this day. Her skirts (and well if they do not throw down some piece of furniture) will at least brush against every article in the room as she moves. Fortunate it is if her skirts do not catch fire, and if the nurse does not give herself up a sacrifice, together with her patient, to be burnt in her own petticoats. I wish the Registrar-General would tell us the exact number of deaths by burning occasioned by this absurd and hid-

eous custom. I wish, too, that people who wear crinoline could see the indecency of their own dress as other people see it. A respectable elderly woman, stooping forward, invested in crinoline, exposes quite as much of her own person to the patient lying in the room as any opera-dancer does on the stage. But no one will ever tell her this unpleasant truth.—*Notes on Nursing.*

**HORRORS OF SWINE AMONG THE SCOTTISH PEASANTS.**—If that animal crossed their path when about to set out on a sea voyage they considered it so unlucky an omen that they would not venture off. A clergyman of one of these fishing villages having mentioned this superstition to a clerical friend, and finding he was rather incredulous on the subject, in order to convince him, told him he would allow him an opportunity of testing the truth of it, allowing him to preach for him on the following day. It was arranged that his friend was to read the chapter relating to the herd of swine into which the evil spirits were cast. Accordingly, when the first verse was read in which the unclean beast was mentioned, a slight commotion was observable among the Scottish audience, each one of them putting his or her hand on any near piece of iron—a nail on the seat or backboard, or to the nails on their shoes. At the repetition of the words again and again, more commotion was visible, and the words “cauld airn” (cold iron), the antidote to this baneful spell, were heard issuing from various corners of the church. And finally, on his coming over the hated word again, when the whole herd ran violently down the bank into the sea, the alarmed parishioners, irritated beyond bounds, rose, and all left the church in bodies.—*Ramsay's Reminiscences.*

**FLOWERS AND FOLIAGE OF INDOOR PLANT CASES.**—Miss Maling in her interesting little work on this subject, recently published in England, brings prominently before us a modified form of glazed case for plants, which is called the Indoor Plant Case, “the original idea of which was of course taken from the Wardian case,” to which the chief addition seems to be the provision of a simple plan for heating, so arranged that the plants may either be cool if they are of a nature to bear a low temperature; or “at 10 minutes's notice the heat can be raised to any degree up to 90 degrees.” When we think of the fleeting plants and flowers that during summer ornament our open drawing-room stands, it must be admitted that something more is wanted. “I have, till quite lately,” writes Miss Maling, “been interesting myself in these cases, contriving to work them up to something like completeness, without much noting the time the flowers lasted; still the lamentations of friends who found time after time this flower and that flower and another flower lasting with me, while

theirs meanwhile had gone through many a change—all this made it quite evident that two months were long for primroses, and five weeks for hyacinths; while for geraniums and gloxinias, fuchsias and begonias, I venture not to speak. I may say, most truly, that I know no other means of keeping flowers anything like so long as two months, either in a drawing-room with its dry air, or in a green-house with its passing currents, and certainly not in a garden bed in the finest season. Yet, after all, the secret is a very simple one. It is merely the stillness around them which preserves the flowers so very long unchanged; while the peculiar arrangement by which the heat is supplied provides that soft, dewy atmosphere in which so many of the prettiest plants delight.”

**UNLUCKY PEOPLE.**—It is a part of the great fact of luck—the indubitable fact that there are men, women, ships, horses, railway engines, whole railways, which are unlucky. I do not believe in the common theory of luck, but no thoughtful or observant man can deny the fact of it. And in no fashion does it appear more certainly than in this, that in the case of some men cross-accidents are always marring them and the effect they would fain produce. The system of things is against them.

They are not in every case unsuccessful, but whatever success they attain is gained by brave fighting against wind and tide.

At College they carried off many honors, but no such luck ever befel them as that some wealthy person should offer, during their days, some special medal for essay or examination, which they would have gained as of course. There was no extra harvest for them to reap; they could do no more than win all that was to be won. They go to the bar, and they gradually make their way; but the day never comes on which their leader is suddenly taken ill, and they have the opportunity of earning a brilliant reputation by conducting, in his absence, a case in which they are thoroughly prepared. They go into the church and earn a fair character as preachers; but the living they would like never becomes vacant, and when they are appointed to preach on some important occasion, it happens that the ground is a foot deep with snow.—*Frazer's Magazine.*

**AMMONIA IN RAIN.**—Any one may satisfy himself of the presence of ammonia in rain, by simply adding a little sulphuric or muriatic acid to a quantity of rain water, and by evaporating this nearly to dryness in a clean porcelain basin. The ammonia remains in the residue, in combination with the acid employed, and may be detected either by the addition of a little chloride of platinum, or more simply by a little powdered lime, which separates the ammonia, and thus renders sensible its peculiar pungent smell. The sensation perceived on moistening

the hand with rain water, so different from that produced by pure distilled water, and to which the term "softness" is vulgarly applied, is also due to the carbonate of ammonia contained in the former—*Liebig's Organic Chemistry*.

**REMEDY FOR COLD FEET.**—It is impossible to have vigorous health if the feet are habitually cold; no amount of external covering can keep them warm. Wearing pepper and other irritants in the stockings, is generally inefficient, is always hurtful in its tendencies, and never accomplishes a permanent radical good. One of the most uniformly efficient means of keeping the feet warm is to wash them in water at least as cold as the atmosphere of the room, night and morning; let it be done within a minute in very cold weather, then wipe and rub them rapidly and thoroughly with a very coarse towel, dress, and when practicable, take a walk or else dry them by the fire, rubbing them well with the hands.

In addition, let half an inch of curled hair be basted to a piece of cloth and slipped in the stocking, the hair touching the soles of the feet to titillate the skin, and thus aid in drawing the blood thither to warm them. The hair conduct, the moisture from the feet to the woollen cloth and thus keeps them dry. These hair-soles should be placed before the fire at night, so as to be thoroughly dried by the morning. Cork-soles absorb moisture from the shoe and the feet also, and require several days to be thoroughly dried. India-rubbers confine the dampness about the feet, hence they should be promptly removed as the wearer ceases walking nor should they be used except in muddy, slushy weather.—*Halls' Journal of Health*.

**HOW THE BIBLE WAS TRANSLATED.**—We are indebted to King James for the excellent translation of the Bible now in use. This version was undertaken by him in performance of a promise made by the King at Hampton Court conference; and Dr. Reynolds, the great champion of the Puritans, by whom it was there suggested, was one of the divines engaged in its execution. Forty-seven of the best biblical scholars undertook the great labour of love, who divided themselves into six classes, each undertaking a portion of the Scriptures. Each member of a class translated the whole of the portion set apart to this class, then the class met, and revised as a body their separate versions. One general version was next agreed upon by the class, which was subsequently revised by each of the other classes. Two of the classes sat at Cambridge, two at Oxford, and two at Westminster. Three years were spent in the undertaking; viz., from 1607 to 1611. The new version was dedicated to the king, and printed by Robert Barker in the year of its completion. The excellence of the translation is universally acknowledged; and though in consequence of the changes which our forms of speech have

since undergone many expressions in it may now appear unrefined or homely, its general effect is far more impressive than that of a more polished translation. Up to the time of James I., all Bibles were printed in German character, or black letter, but, after that date, the Roman letters (as now employed) were adopted, and soon superseded the old-fashioned manner of printing. The appearance of King James's Bible formed almost on the most important events in the history of the English language; it had the immediate effect of recommending to common use a very considerable number of words derived from the learned languages, for which the translators had been unable to find equivalents in the current English of the time. At present it performs a service of an opposite nature, and keeps in use, at least in remembrance, many valuable words and expressive idioms which would otherwise have been rejected with disdain by the fastidiousness of modern taste as homely and familiar.—*Englishwoman's Domestic Magazine*.

**SMOKE-HOUSES.—HOW SHOULD THEY BE BUILT?**  
—A smoke-house should be square, its size varying from four to eight feet in diameter, according to the quantity of meat required to be smoked; the lower portion to the height of five feet should be of brick, with a door lined with sheet iron. This part may serve both as an ash-house and as the proper place for the fire to furnish the smoke. Fire should be placed in the middle and covered with the material to be burned, so that the mass being surrounded by ashes, may maintain the ignition for a long time, giving off the smoke with regularity. The upper part may be wood, and the separation from the lower part by joists, covered with scantling, so as to leave spaces averaging three inches in diameter for the ascent of the smoke. The height of this upper portion may be four feet, beside the ascent of the roof, and should be furnished with a door that may be locked, so that the door of the lower portion will not give ingress to the meat-room. This separation between the two portions will catch any piece of meat that may accidentally fall, while the lower portion need not be locked, so as to enable the frequent removal of ashes from the house, and the proper attention to the fire to be more readily performed. Saw-dust placed over a few ignited coals will furnish the necessary material for smoking the meat. The saw-dust however, should be from such wood as is most free from resinous matter. The pyroligneous acid evaporated is of a better flavour from hard than from the soft woods, while the amount of creosote, which is the preservative property, will be the same.—*Working Farmer*.

**DIFFERENT MODES OF WALKING.**—We have little difficulty in recognizing three chief classes among pedestrians. First, there are those who

walk with a pompous strut, or a mincing gait, or affect some style or other. We are naturally very little inclined in favour of such persons; indeed, we have usually to make an effort not to be decidedly prejudiced against them. Secondly, there are those who pay too little attention to their movements, who do not seem to be sufficiently alive to the responsibility attaching to the possessors of so noble a structure as the human frame, and who do not give themselves the trouble to exert the powers of the glorious mechanism with which they are charged. They slouch, or dawdle along in a listless, lazy manner. Instinct tells us rightly to beware how we trust such persons with the conduct of our affairs, or with any office of responsibility. We feel that the lack of energy manifested in the guidance of their limbs is, too probably, a feature of character which unfits them for the active duties of life; and we know that such men are not usually successful in their calling. Thirdly, there are those who show, by the firmness and precision of their step, and by the regularity in the succession of their movements by which the step is made, that they are conscious of the dignity of their species, of the responsibility attendant on that dignity, and of the respect due to themselves. Such men, we feel, are likely to pursue their avocations energetically, and methodically, as well as with punctuality. Many points of character peep out in the way men walk. Our poet tells us that in one we may read

“rascal in the motions of his back,  
And scoundrel in the supple sliding knee.”

Another has a halting, shuffling, undecided gait; while a third walks in a bold, determined, straightforward, erect and independent manner. One has a cautious, parsimonious step, as if sparing of shoe leather, or afraid to trust the ground: he has, however, probably trusted the funds with considerable investments. Some walk with long pretentious strides; others make short, quick, insignificant steps. Some, again, are hurried, fussy, noisy; while others glide along in a quiet, shrinking, unpretending—it may be timid manner.—*The Human Foot.*

A SOUTHERN PLANTER'S HOME.—It is quite in the suburb, near the second Bayou; a great shapeless road, ankle deep in white dust, lies before it, fringed by those loathsome open drains that are the curse of New Orleans and the chief originators of the yellow fever. In this road negro children roll and scramble, and pigs rout and grunt. Before Mr. Quackenboss's house there is a row of huge magnolia trees, at this time covered with tufts of pink and scarlet flowers, which contrast beautifully with the small dark myrtle green leaves. My hospitable friend pushes open a wicket gate, and we pass up a garden walk and enter the cool verandah'd house. Mrs. Quackenboss and the little Quackenbosses are on a visit to Cuba, so we are alone.

My friend claps his hands and a negro boy appears, receives an order, and returns in a few minutes with two bottles of German wine, a bowl of sparkling ice, a box of cigars, and some tumblers. My friend gave a sigh of satisfaction, took up with an air of reflection a feather fan of Mrs. B's that lay on the table, spat three times at a special knot on the floor, and throwing his feet over the back of a very high chair, began to open the conversation on the subject of the cotton supplies of England,—*Dickens's "All the Year Round."*

EXISTENCE.—It is an unquestionable fact that those who are equally acquainted with, and equally capable of appreciating and enjoying both, do give a most marked preference to the manner of existence which employs their higher faculties. Few human creatures would consent to be changed into any other animals for a promise of the fullest allowance of a beast's pleasures; no intelligent human being would consent to be a fool, no instructed person would be an ignoramus, no person of feeling and conscience would be selfish and base, even though they should be persuaded that the fool, the dunce, or the rascal is better satisfied with his lot than they are with theirs. They would not resign what they possess more than he for the most complete satisfaction of all the desires which they have in common with him. If they ever fancy they would, it is only in cases of unhappiness so extreme, that to escape from it they would exchange their lot or almost any other, however desirable in their own eyes. A being of higher faculties requires more to make him happy, is capable of more acute suffering, and certainly accessible to it at more points than one of an inferior type; but in spite of these liabilities, he can never really wish to sink into what he feels to be a lower grade of existence,—*"Utilitarianism" in Frazer's Magazine.*

THE PUBLIC HEALTH.—INFLUENCE OF THE SEASONS ON THE HUMAN SYSTEM.—Dr. Edward Smith, F. R. S., delivered, at the meeting of the British Association at Manchester, a lecture upon this subject. The observations he made were to show the variation of the vital action in the human system, and his two principal inquiries referred, the one to the respiratory functions, and the other to the elimination of nitrogen. In reference to respiration, the amount of carbonic acid evolved varied from day to day with the cycle of the seasons. He had found that there was a definite variation in the amount of vital action proceeding within the body at the different periods of the year, and this showed a well marked course. Thus, at the beginning of June a fall commenced, and this continued and progressively increased through June, July and August, until the commencement of September, when the lowest point was attained. After this period, in October an upward tendency was manifested, and it continued

through October, November, and December, until January, when a point was attained from which there was little variation in January, and March. In April and May the amount of carbonic acid evolved was yet further increased until the point was reached whence he started. The extreme amount of change observed was a loss of three grains of carbonic acid gas per hour from the commencement of June to Sept.; and the extreme quantities recorded were in May 10.26 grains, and at the lowest period between six and seven grains. The rate of respiration, the quantity of air inspired, and the quantity of carbonic acid exhaled, followed the rule he had explained. It had been proved by several series of experiments that the rate of pulsation was increased by heat—the rapidity of pulsation was the converse of the rate of respiration. With reference to the evolution of nitrogen the conditions were the opposite of those of the elimination of carbonic acid. The general results he had arrived at were, that there was a greater amount of fluid evolved in the summer months than in the winter. The carbonic acid evolved decreased with the increase of temperature. On a sudden increase of temperature there was a large decrease of vital action, and on a fall of temperature there was an increase of vital action. The greatest growth of animals would occur at the period of the year when there was the largest amount of vital action; and in this respect they had connected the animal with the vegetable kingdom. He believed that this was the fact with regard to the growth of children—that they grew at a greater rate in spring than in winter. From facilities which the Registrar-General had afforded him, he had ascertained that a much larger number of those children born at the latter part of summer died within a year of birth than took place amongst those born at other periods of the year. The children born in the winter and spring period were less subject to disease, and in a probability, had stronger constitutions than those born in the summer season. These variations in the increase and decrease of the vital power of the system seemed to him to be the origin of diseases, especially those that were chronic. All epidemics, to a large extent, in whatever part of the world they occurred, took place at the period when the human system was decreasing in vital action. This rule applied to cholera especially, which generally attained its greatest height in June, in October diminished, and in November disappeared."

#### ADULTERATION OF ARTICLES LIABLE TO DUTY.

—The report of Mr. Phillips, the head of the laboratory department of the Inland Revenue, has just been published for the year ending the 31st of March. He states that the analyses made during the 12 months amounted to nearly 11,000, and that the officers have become so efficient that although some of these analyses had

to be sustained in courts of justice, not an instance has occurred of any one of them having been shown to be wrong. The articles on which Mr. Phillips specially reports are tobacco, snuff, pepper, coffee, beer and hops, and malt. With regard to tobacco, it is stated, that although it would be absurd to suppose that the smuggling and adulteration of an article subject to a duty of about 700 per cent. upon its cost can be entirely prevented, there is reason to believe that frauds are rare, and that the revenue from this article is comparatively well secured. An inspection of most of the tobacco manufactories in Ireland, and of many of those in England, during the year, has taken place without the discovery of a single practice that could be deemed illicit. Of five adulterated samples purchased, it is to be presumed, of retail dealers, the illicit materials consisting of burdock, colts-foot, and cabbage leaves, sugar, common salt, and oil. Of snuff it is stated that owing to the great diminution which has taken place during the last four or five years in the adulteration of this article, it has been found necessary to examine only ten samples. Of these, three, which all came from Ireland, proved to have been sophisticated with peat-moss and ground Pinewood Pepper, it is believed, is still extensively sold in that the prevalence of the fraud is mainly due to an adulterated state, and Mr. Phillips considers the practices of some wholesale dealers in and grinders of the commodity. "The skilful and almost scientific manner in which the pepper was so adulterated," he says, "and the care which is taken to render detection difficult and conviction doubtful, are alone sufficient to point out the source, as it is always easy on analysis to distinguish between the highly-finished article of the wholesale delinquent and the bungled production of the unscrupulous retailer." The illicit materials detected in the samples examined during the past year were rice, husks of red and white mustard, sago starch, and the starch of cereals. Coffee also continues to be extensively adulterated, and it is to this that the fact of the consumption not having increased during the last 14 years, in face of a reduction of duty, is supposed to be attributable. Chicory is the material almost universally employed, and within the past 12 months numerous samples which had been purchased as pure coffee have been analysed in the laboratory, and found to contain from 30 to 86 per cent. of chicory. From Glasgow and some other towns in Scotland many samples which were bought at the rate of 1s. 8d. per lb. having been found to contain from 50 to 70 per cent., and in one instance 84 per cent. of chicory. In samples sold at 1s. 4d. avowedly as mixtures of coffee and chicory, there is really it is said, no limit to the proportion of the latter, and instances occur in localities chiefly inhabited by the very poor, where the samples prove to be composed of it entirely. Out of

many thousand analyses, it has been found that on an average, more than 29 per cent. of samples sold as pure coffee were adulterated with chicory, while of those sold as "mixtures of coffee and chicory," the proportion of chicory was more than 39 per cent. This is greater than in previous years, and Mr. Phillips remarks that it "at once gives the clue to the causes which are in operation in keeping down the importation of coffee."

#### SUNSET IN THE NORTH-WEST HIGHLANDS.—

Among the many contrasts which geology delights to conjure up to the imagination, few are more striking than that which comes before us amid the wilds of Skye, or the glens of Mull. To sit in the light of an autumn evening, as we have often done, and mark the sinking beams as they strike along the sides of those truncated pyramidal hills, revealing terrace over terrace in alternate bars of dark crag and green slope—features that are but faintly seen in the glare of noon-day; to cast the eye to the right hand and to the left over the wild heathy uplands that stretch around in utter solitude and stillness, and to watch how hill-top after hill-top loses its blush of sunset, and how the chill shadows struggle upward from dark and lonely glens, and then, as the sun dips under the Atlantic, and all the landscape around is suffused with a cold grey hue, and the night begins to descend, to bethink us how these hills arose, and in what a far distant era; how they were heaved out as burning rocks from subterranean abysses, and rolled over river and sea; how sheet after sheet was piled upon submerged estuaries, with their shell banks and fringing forests; how, again, on the cooled and hardened lava, as it sank beneath the waters, animal life flourished as abundantly as before, and new forests sprang up as luxuriant as those which had preceded them; to reflect how different were the forms both of animal and vegetable life from those which characterize the district now; and then letting our imagination drift down the long cycle of ages and mutations that succeeded to those of the oolite, to find ourselves once more among the heathy hills of the Inner Hebrides, as the dark night-dews begin to fall—this is a train of reverie which, in spite of what may be said by the strict and formal *savant*, is to some minds as natural as it is pleasant and useful, for it gives life to the dead past, by linking it in with the living present; it expands our appreciation of the existing world, by showing us how the features of that world have arisen; and by thus uniting us with past and present, with the immeasurably ancient and the comparatively new, it enlarges our views of nature, and makes us feel in a novel, but not the less impressive manner, that there is a unity in creation—a sympathy which, in a way we know not, binds all things to each other, and to Him who is at once their author and their end.

—*North British Review.*

#### Farming in Devonshire.

[From Maxwell's *Sighs, Smiles, and Sketches.*]

A. D. 1861.

Come, wife, 'tis time for we to rise,  
The clock is striking five :  
Be quick and get the tateses fried ;  
Now do, lass, look alive.  
I've got to put my barley in .  
And now the first of May's come ;  
I don't know how us shall get on,  
If many rainy days come,  
I've got to cart out all my dung  
And lime to till the tateses ;

The land's as wet as wet can be.  
How bothered my poor pate is !  
There's Brisk and Boxer cruel galled,  
And Tidy Mare is gripy ;  
And oats are down, and wh'at's a'valled,  
And Roger's always swipy ;  
And all the sheep have got the scab,  
And wool's a going down ;  
And I've to draw my produce in,  
Vul vourteen miles to town.

And Lady-day's a'come and gone,  
And I've not paid my rent yet ;  
And Bill, and Jan, and little Joe  
Ha' ne'er to school been sent yet.  
Us cant get on if times don't mend—  
'Tis raly quite alarming :  
I only wish my lease was out,  
I'm zure I'd give up farming.

A. D. 1900.

Matilda ! order chocolate ;  
I'ts nearly ten o'clock ;  
And getting up at half-past eight  
Is really quite a shock.  
I worked so hard till nine last night,  
To prove that last analysis,  
That, should my brain be further tried,  
I really fear paralysis.

Well, I'll just take a quiet ride ;  
James, bring my locomotive—  
That half-horse power, with trotting springs  
Of health 'twill be promotive.  
And, James, do fetch a gallon of  
Concentrated Thames water ;  
I'll just top-dress my cucumbers—  
Five acres and a quarter.

Well, here I'm back ; I've been all round ;  
The farm is looking splendid  
What fools they were, some years ago,  
To work as hard as men did !  
I've heard my grandsire say, his dad  
Met with some dreadful losses :  
No wonder, when they used to work  
With those great horrid hosses.

And, James, just touch the telegraph,  
 And bid my engineer  
 Turn out six dozen ploughs next week,  
 To get the breaches clear;  
 And tell professor Faraday,  
 And my sub-chemist, Jones,  
 To forward, by next Monday's post,  
 Their last extract of bones.

'Tis time I got my turnips in;  
 I should not like to mess it;  
 And as I've only one square mile,  
 There'll be enough to dress it,  
 And, James, do turn the battery on,  
 The wheat is just in flower,  
 And give it one galvanic shock;  
 It wants a gentle shower.

And syringe all the cabbage plants  
 With essence of guano;  
 And ask Miss Jane to milk the cows  
 With the new "vaccine piano."  
 And, James, fetch down my last balloon,  
 With speed-retarding crupper,  
 I'm going to Barnet fair to-day,  
 And shan't be back till supper.

### An Interesting Sheep Experiment.

In Scotland as well as England it is well known there is great attention paid to sheep-breeding, both for the wool and flesh; indeed, there is no country in the world where success has been so great and gratifying. Our best breeds of sheep are obtained there; but we have found that the mixed breeds do better with us in the long run than the pure imported stock. The following experiments, undertaken by the Parlington Tenant's Club of Scotland, as we find it reported in the *Scottish Farmer*, to prove the fattening qualities of certain breeds, will be read with interest. A stone is 14 lbs.)

There was eight different kinds of sheep, and each lot were turned into a two-acre plot of a 16 acre field, each plot being of equal grazing value. The lot consist of—1st, ten crosses from the Teeswater with the Leicester; 2nd, twelve crosses from the Cheviot with the Leicester; 3d, ten Lincolns; 4th, ten South-Downs; 5th, ten Shropshire Downs; 6th, twelve Leicesters; 7th, ten Cotswolds; and 8th, seven odd sheep, one from each of the above classes—all hogs. The fairness of the above trial would thus appear to be somewhat vitiated by the difference in the numbers. The cross Cheviots and the Leicesters would have a sixth less, grass than five of the other lots, and five-twelfths less than the odd sheep.

The lots were all turned into grass on the 23d of May. A fortnight after this they weighed. The weight of the Teeswater crosses were 106 stones 3 lbs.; of the Cheviot crosses, 124 stone 13 lbs.; of the Lincolns, 125 stone 9 lbs.;

of the South-downs, 95 stone 10 lbs.; Shropshire-Downs, 101 stone 6 lbs.; odd sheep, 69 stone 7 lbs.; Leicesters, 116 stone 3 lbs.; and Cotswolds, 90 stone 9 lbs. Between this date and the fourth of October the Sheep were weighed four times. After four months' grazing, supplemented by 3 lbs. of linseed cake per day, from 17th June to 1st August, and thenceforward with 6 lbs. per day of the same materials, it was found that the Teeswater crosses had added 18 stone 1 lb., or nearly one-sixth to their original weight; that the Cheviot crosses had added 18 stone 9 lbs., or little more than one-seventh; the Lincolns 6 stone 7 lbs.; or about one-twentieth; the South-Downs, 13 stone 2 lb., or less than one-seventh; the Shropshire-Downs, 20 stone 8 lbs., or about one-fifth; the odd sheep, 11 stone 10 lbs.; or almost one-sixth the Leicesters, 24 stone 71 lb., or nearly one-fourth; and the Cotswolds, 19 stone 6 lbs., or more than one fifth of their original weight. The advantage is thus in favor of the Leicesters and Cotswolds. The Cheviot crosses, however, do not seem to have had enough of grass, having decreased instead of gaining in weight during the last month.

One sheep of each kind was tried on grass without any artificial food. Under these conditions, the Cheviot and Leicester cross greatly surpassed all the rest, making three stones in four months.

The grass eaten is, of course, an item, when profit, comes to be calculated, and the Cheviot crosses appear to be the greatest consumers. Next to them the Lincolns and Shropshire-Downs bared their pasture most, and after them the pure Leicesters and Cotswolds. The fact that the sheep were not all in the same condition when procured, must also affect the experiment to some extent, but it is to be commended as a step in the right direction.

**REMEDY FOR SLEEPINESS IN CHURCH**—The art of balancing has become quite popular, and has been deemed worthy of explanation in the form of a lecture by the scientific Mr. Pepper, who is smart and learned at the same time. We must extract one of the little jokes with which he peppered his lecture and made it most acceptable fare: he said the old monks' seats in Westminster Abbey, in Henry VII.'s Chapel, were placed on an axis which passed through the centre. As long as they remained awake nothing happened, but directly they went to sleep the seat upset and they were tumbled out. This unclerical merriment was also provided for at the church at Bishop's Stortford, where the seats were similarly constructed. The idea is worthy of introduction into some of our modern "sensational" churches.—*Court Journal*.

**ANTLERS OF THE STAG**—There is no comparison, as regards size, to be made between the antlers of the present and of former centuries, so greatly inferior are those which we have to

those which have been; and it is quite natural that it should be so. Not only did the deer formerly reach a greater age, but they had better and more abundant pasturage than now, when the woods are cut down, and the land is highly cultivated. Abundance of nutritious food produces generally antlers of large growth.—*Forest Creatures*

### BOARD OF AGRICULTURE.

THE Office of the Board of Agriculture has been removed to 188 King Street West, a few doors from the late location adjoining the Government House. Agriculturists and any others who may be so disposed are invited to call and examine the Library, &c., when convenient.

Toronto, 1861.

HUGH C. THOMSON,  
Secretary.

### Notice of Co-Partnership.

THE Undersigned have entered into Partnership as Seedsmen and dealers in all kinds of Agricultural and Horticultural Implements, under the firm of James Fleming & Co.

JAMES FLEMING,  
GEORGE W. BUCKLAND.

### NOTICE.

JAMES FLEMING & CO., Seedsmen to the Agricultural Association of Upper Canada will carry on the above business, wholesale and Retail, at 126 Yonge-st., 4 doors North of Adelaide-street, until next July, when they will remove to the new Agricultural Hall, at the corner of Queen and Yonge-streets.

JAMES FLEMING will continue the business of Retail Seedsmen and Florist at his old stand, 350 Yonge-street.

Toronto, January 1st, 1861.

### FOR SALE.

AT

WOODHILL, WATERDOWN P. O.

MR. FERGUSSON expects to have several pure *Durham* bull calves to dispose of next Spring, 1862, not intending to raise any this season. These calves will be all of the well known *DUCHESS* tribe, and will be put on the G. W. R. R. at six weeks old for eighty dollars each.

N. B.—First come, first served.

Waterdown, Nov. 14, 1861. 4-t.

### THOROUGH BRED STOCK FOR SALE.

THE SUBSCRIBER has for Sale Durham and Galloway Cattle, male and female.

Leicester, Cotswold, and Lincolnshire Sheep, male and female.

January 1, 1862.

JOHN SNELL,

tf.

Edmonton, P. O., C. W.

**VETERINARY SURGEON.**

**A**NDREW SMITH, Licentiate of the Edinburgh Veterinary College, and by appointment, Veterinary Surgeon to the Board of Agriculture of Upper Canada, respectfully announces that he has obtained those stables and part of the premises heretofore occupied by John Worthington, Esq., situated corner of Bay and Temperance streets, and which are being fitted up as a *Veterinary Infirmary*.

Medicines for Horses and Cattle always on hand. Horses examined as to soundness, &c.

Veterinary Establishment, Corner of Bay and Temperance Sts.

Toronto, January 22nd, 1862.

**FOR SALE.**

**A FEW PURE-BRED SOUTH-DOWN RAMS**  
and Ewe Lambs, from

**IMPORTED STOCK,**

Selected from the Best Flock-dealers in Dorset, Wilts, and Hants.

The Subscriber will Warrant these Lambs to produce as much Wool and Mutton, and of equal Quality, as those of Jonas Webb, or any other Flock of the same kind and number in England.

JOHN SPENCER,  
Brooklin, Post Office,

Oct. 12th, 1861. Ontario County C. W.

**The Germination of Seeds.**

The season is now close at hand when the ground has to be prepared for the reception of the seed of the various descriptions of spring crops. Every farmer or gardener is aware how much depends on bringing the soil into a proper tilth by ploughing, digging, harrowing, &c., processes which, if neglected, or imperfectly performed, will be sure to affect the bulk and quality of the crop. A certain depth of friable and finely-reduced earth, readily admitting air, warmth, and moisture, is as necessary to the growth and development of the cultivated crops as are the various ingredients of an organic and inorganic nature that constitute plant-food, and which, if it does not already exist in the soil, must be supplied artificially in the shape of what is well known under the name of manure. At present we propose to consider the earliest stage of development in the life of a plant and the conditions or agents which affect it, usually designated *germination*. A cursory view of this interesting subject will afford the practical man several useful suggestions, as well as pleasing evidence of the wisdom and goodness of creation and power.

The growth of the seed consists in the development of the germ into a perfect plant, and is known as *germination*. Supposing the conditions of growth to be favourable, the first preliminary is a softening of the coat of the seed, by which means water gains an entrance, and having pervaded the mass, causes it to swell freely. When the water reaches the germ of

the seed, the gluten or albuminous matter near to it undergoes a chemical change, and we have a very important and powerful body formed which is called *diastase*. Whether or not the germ in any way participates in this change, we have no proof; but, if not, it is certain that at least by its presence it exerts a controlling power. The same addition of moisture to any other portion of the seed would not produce the same effect, for this agent (*diastase*) is only found in close proximity to the germ, and its existence in the seed appears to be simultaneous with the first stage of germination. Upon the *diastase* thus formed devolves the important office of preparing food for the growth of the germ; for the bulk of the seed, although abundant in quantity, and exactly suitable to its constituent elements, is not ready for use until it has become soluble in water, and thus been made capable of entering into the circulation of the germ. This is accomplished by means the *diastase*, by the agency of which the necessary supplies are prepared, so long as the store of food in the seed is needed. An immediate extension of the cellular matter accompanies the entrance of the food into the circulation, and we have the external evidence of life by the sprouting of the seed. In whatever position the seed may be placed, the radicles at once strike perpendicularly down into the soil, and the tender rootlets fix themselves there with but little delay. As soon as this is effected, the gemmule grows in the opposite direction, and becomes developed into the stem and leaves of the plant.

The conditions which control the growth of seeds are, the presence of air, moisture, and warmth; and, to produce healthy germination, all are required in definite proportions. When seed is protected from these agencies it will retain its powers of growth for long periods of time. Thus, wheat, preserved in Egyptian mummies between 3000 and 4000 years, has, after the lapse of time, germinated and produced a large increase. The preservation of the power of growth is entirely dependent upon the soil being kept from those agencies which would excite its vital energy,—moisture is the first essential for germination, as it is in consequence of the chemical action excited in the seed by the entrance of water that the seed is aroused to action; and after this process of growth has been excited, if it become checked, it cannot be renewed. This shows the necessity of keeping seeds dry when they are not required to germinate. Moisture alone is not sufficient for the process of growth, as the seed requires a supply of atmospheric air to enable the necessary chemical changes to proceed. Stagnant water in the soil must of necessity be unfavorable to germination, because it renders the land cold, and excludes the free access of air, both of which conditions are prejudicial.

The exceptions to this rule are very few; one, however, may be found amongst agricultural seeds in the floating sweet water-grass (*Glyceria fluitans*), grown in water meadows, in which instance immersion in water is absolutely necessary for the growth of the seed. In this case we have a seed which has the power of extracting its supply of air from water,—a power which very few other seeds possess. The supply of air is as necessary for these aquatic seeds as for any others; for if we drive out the air from water by boiling, they can no longer germinate. For the same reason, seeds which are buried deeply in the earth remain there for many years, not because they want moisture, but because it is unaccompanied by the presence of atmospheric air. The earth raised from wells, or brought from railway cuttings, or ploughed up by a furrow of extra depth, often becomes covered by a growth of vegetation, the produce of seeds which have long been dormant in the soil.

Warmth is another essential condition of germination, which, within moderate limits, is rendered more rapid by an increase of tempera-

ture; but it must be accompanied by a proportionate increase of moisture, otherwise it becomes destructive. The action of heat promotes chemical changes in the seed, but a free supply of water is necessary, not only that it may exert a like chemical influence, but also because it enters largely into the most delicate body into which the dry matter of the seed has to be transformed. Thus we see that healthy germination depends upon the combined action of the three agents—heat, water, and air.

The opinions which are entertained respecting the influence of light are conflicting. Some consider that light retards the process of germination, whilst others consider that it does not influence it prejudicially. The experiments which have been made, although far from conclusive, are calculated to favour the former opinion; for the growth, although equally perfect, has not been so rapid under the action of light as when the seed has been covered from it. We know that, as soon as the seed has made sufficient growth to throw out its leaves, the action of light is favourable, its presence enabling the plant to decompose carbonic acid and to retain the carbon for its own, whilst the oxygen is thrown off into the air. But at this earlier stage of existence,—or, in other words, during the period of germination, growth is favoured by an action *just the reverse* of this. The seed and its sprouts want to absorb, not to throw off oxygen, and to emit instead of taking in carbonic acid. During germination, then, the action would tend to paralyze the vital powers of the seed, and limit its growth to the hours of darkness instead of allowing the development to be continuous. Another great advantage gained by covering the seed is the more equable supply of moisture which is preserved beneath the surface, as well as the better opportunity afforded to the roots for firmly fixing themselves in the soil. Those who are practically engaged in conducting the operations of the farm or garden may gain much insight into these interesting but somewhat intricate matters, by frequent and accurate observations, from the sowing of the seed, through all the successive stages of its development to the perfect maturing of the crop, and comparing the results obtained with the principles laid down by the teachings of chemical and physiological science.

### Agricultural Hall, Toronto.

This building occupies a plot of ground on the North side of Queen Street, at the corner of Yonge Street, and as it is situated in one of the principal thoroughfares of the city, public curiosity may be gratified by a sketch of the design. We have been favoured with a sight of the plans and elevations, and the following description (drawn up on the supposition that the building were completed, which it will shortly be) will be found pretty accurate :—

The front to Yonge Street is 41 feet in length, and the façade to Queen Street is 82 feet. It contains on the ground floor—at the angle of the two streets—a substantial and excellent warehouse, for the sale of seeds, plants, &c., with a smaller store entering from Yonge Street, which will be rented to a suitable party. The Entrance to the Offices and museum is in the centre of the Queen Street front, whence a large and roomy staircase leads to the first floor, on which is the Board room, lighted by two large windows on the Yonge Street front, Secretary's room, and Porter's room, also a large and commodious store room, connected with the seed store on the ground floor. The entire of the upper floor is in one large apartment., the internal dimensions of which are 79 feet in length, by 38 feet in width. The side walls are 19 feet in height from the floor to the top of cornice. The roof is in one span, the framed trusses being wrought, having curved wall-braces springing from moulded and carved stone corbels. The ceiling rises from the side walls at an angle of about twenty-seven degrees, being in the centre 25 feet from the floor to the ceiling. It is divided by moulded ribs into panels, with plaster mouldings and enriched centre pieces, which are perforated for ventilation. This spacious apartment is intended as a museum, for agricultural implements, patented inventions, and other articles connected with agriculture, and open to the public, free of charge. This it is considered will be a great boon to farmers and others, interested in the progress of agriculture, where the utility and economy of the several implements exhibited may be studied.

The building is constructed in the Italian style of architecture. The principal fronts are faced with the best red pressed bricks, and the

ornamental masonry and other dressings are of Ohio stone. The entrance door,—which, as already remarked, is in the centre of the Queen Street front—has rusticated and moulded stone jambs, semi-circular head, with radiating rustics. On either side of the door-way are two windows with semi-circular stone heads. Over the ground floor windows there is a bold belting course, which will be enriched by parti-coloured mosaics, a system of decoration which we believe has never been attempted in this country, although in English and other European cities, it is much used for external and internal decorations. The windows of the first floor rest on moulded sills, with small cast iron balconies in front of them, the windows having stone jambs and massive cornices. Over these are moulded consoles, supporting the balconies, in front of the upper row of windows, which are finished with handsome stone facings; the whole being surmounted by a bold and enriched cornice, producing an excellent effect. While the general symmetry is well preserved, the disposition of the windows, and the great proportion of solid wall, contribute to give the building a massive character. In this respect alone the design exhibits some novelty and piquancy, particularly in the centre compartment, where the five openings are brought pretty closely together, leaving a large pier on either side of the adjoining opening. Thus the front may be said to be divided into three main compartments, the centre being greater than the other two, which assume the appearance of wings; producing a good architectural contrast, combining solidity and strength—yet without either blankness or heaviness. The plans of the building have been furnished by Mr. Joseph Sheard, architect, under whose superintendence the works are being carried out. The contractors are, for the brick-laying and masonry, Mr. John Platt; and for the joiner and carpenter work, Mr. John Harmer. The painting will be executed by Mr. Alexander Hamilton. The whole expense of the building will not exceed the original estimate of \$12,400.

The principal object of the Board in erecting this capacious and commodious building is to secure a permanent office for the transaction of its increasing business; much inconvenience having been hitherto experienced from inadequate accommodation, and frequent removals.—

In the preamble of the Agricultural Statute, 20 Vic., cap. 32, among the objects which the Board is required to promote, is the establishment in Toronto, of a public Library of reference, comprising both agricultural and horticultural publications, and also a Museum, embracing both those departments of industry. The former has already, to some extent, been accomplished, the nucleus of a library having been formed; but for want of adequate accommodation of a permanent nature, the latter has necessarily been kept in abeyance. It is intended that the capacious Hall set apart for a Museum, shall comprise characteristic specimens of the natural as well as the cultivated productions of Canada; implements and machines, or their models; specimens of soils, and their related rocks and minerals; with whatever can throw light on the agricultural condition and capabilities of the Province. The Board will therefore have to appeal to farmers and others interested in these important objects, (and who is not?) to assist in carrying them to completion. Our agricultural Societies should see that the choice productions of their respective localities are represented in this collection; and horticulturists it is hoped, will follow their example. The firm of James Fleming & Co., will always keep an extensive and reliable assortment of all kinds of agricultural and garden seeds, suitable to this climate; and they intend, we understand, to form a Depot for the various implements and machines belonging to the departments of industry. Numbers will doubtless visit the Agricultural Hall for purposes of business or enquiry, and there can be little doubt that this new enterprise of the Board will be found in its practical working of great general convenience and public advantage.

### An Experiment of Wheat Growing in 1766.

In the *Gentleman's Magazine* of May 1770, the following statement appears of the wonderful power of increase which the wheat plant possesses when subjected to extraordinary treatment:—

"In the autumn of 1765 and spring of 1766, Mr. Miller, of Cambridge, produced 2000 ears of wheat from a single grain, by dividing and transplanting it. He repeated his experiment in June, 1766, with yet greater success.

"He sowed on the 2nd of June some grains of the common red wheat; on the 8th of August he took up a plant and divided it into eight parts, each of which he planted again separately; by the middle of September they pushed out several side shoots, and were again divided into 67 plants; these plants remained through the winter, and were then divided into 500; they soon became stronger than many in the wheat-field, and some of them produced 100 ears from a single root. Many of the ears were 7 inches long, and contained between 60 and 70 grains. The whole number of ears produced by this process from a single grain was 21,109, which yielded three pecks and three quarters of grain, and the number of grains being about 576,800.

### The Provincial Exhibition of 1862.

The Local Committee for the Provincial Exhibition at Toronto this year have been appointed, and have already held several meetings. The committee consists of the following gentlemen:—

F. W. Jarvis, Esq., Sheriff York and Peel; J. P. Wheler, Esq., Warden, York and Peel; J. G. Bowes, Esq., Mayor of the City of Toronto; Hon. G. W. Allan, President Toronto Horticultural Society; Jas. Beachall, Esq., President Toronto Electoral Division Agricultural Society; The President of the Mechanics' Institute of Toronto; Aldermen Brunel, Carr, Strachan, and Hynes; Professor Croft; Professor Hind; Captain Shaw; Arch. Barker, Esq., Markham; J. P. Bull, Esq., York township; together with all the members of the Board of Agriculture, *ex-officio*. Chairman of the committee, Hon. G. W. Allan; Secretary and Treasurer, Wm. Edwards, Esq. The committee have commenced work energetically, and we hope that those on whom the exhibition must mainly depend for the material elements of success, we mean the producers of the country, the stock breeders, farmers, gardeners, mechanics and artisans, will not be behind hand in their preparations to carry out their part of the programme.—The Prize list will be published as early in the season as possible, but in the mean time the lists of previous years will serve very well as a guide. The subjoined letter from Mr.

Denison, who is on the committee as a member of the Board of Agriculture, will give some idea of the preparations the Local Committee propose making.

## PROVINCIAL AGRICULTURAL ASSOCIATION.

TORONTO LOCAL COMMITTEE.

### *Editors of Agriculturist,*

Farmers who intend to exhibit at the Provincial Agricultural Show this autumn at Toronto will be glad to learn, that extensive preparations are being made, to accommodate stock, far beyond any ever before prepared at such exhibitions in this country.

1. *Horse Stables*.—Four buildings to be erected in the form of a quadrangle, each building to be 130 feet by 30 feet, and 12 feet high, and divided into double and single stalls. Doors well hinged and furnished with hasped staples,—exhibitors to furnish their own locks. These stables are to be permanent and well lighted and ventilated, and are to be built with the view of accommodating cavalry and artillery in case of necessity.

2. *Cattle Stables* are to be also four in number, 150 feet by 30 feet and eight feet walls. These buildings are to have an eight foot passage through the centre which will leave the stalls 11 feet deep on each side, the outer walls and partitions are to be only 3 feet 6 inches high—the walk down the centre to be raised 2 feet to give a commanding view over the stock. These stable are calculated to hold 26 Durham bulls, 20 Down bulls, 12 Ayrshire bulls, 12 Galloway bulls, and 5 Hereford, 60 Durham cows and heifers, 50 Devon, 30 Ayrshire, 30 Galloway, 20 Hereford, altogether 265 stalls. This building also to be permanent.

3. *Sheep Folds*.—A building 900 feet long, 12 wide, and 7 high, divided into 150 pens, to accommodate 600 sheep, the whole to be covered and partitioned 3 feet high, with movable bars in front, to put the sheep in or take out.

4. *Pig-Pens*.—This building is to be covered and divided into 150 pens 6 feet square, calculated to hold 300 pigs.

5. *Poultry*.—This shed is to be 100 feet long and 12 wide, and the walls are to be 7 feet high, open all around, and to be furnished with two rows of coops down the centre, and three coops high, with lattice fronts, and furnished with doors.

6. *Machine Shed*.—This building is to be 256 feet long, 32 feet wide, and 12 high, good shingle roof, and strongly framed, to stand on cedar posts without sills, to be open and accessible on all sides, and fitted up with a line

of shafting at least 50 feet long, and to be a permanent building.

7. *Forage Barn*.—To contain hay and straw, and fitted with bins for bran and oats, and to be convenient to the other buildings.

8. *Hurdles*.—There will be in addition to this accommodation, sufficient hurdles on the ground to make a hundred pens if required.

It is intended by the local committee, if not by the Corporation, to enclose 8 or 10 acres of land more than we had under fence at the last Exhibition in Toronto. This of course will afford ample room for every purpose, and make the show ground a more convenient shape than before.

Before closing I would advise all friends of the Agricultural Association who have suggestions to offer with regard to the prize list for the current year, to do so at once, before the prize list committee set to work to revise. These suggestions should be forwarded to the Secretary of the Board of Agriculture, Toronto.

It is much to be desired that we have a good show this year. The country never was so full of good stock before, and prosperity is fast returning; indeed we were never in a better position to get up a good show than now. The location is central and accessible, having Rail Roads and Steamers in all directions, the heart of an old settled country, well filled with good stock and good farmers, and nothing can prove a good farmer better than giving a hearty support to our own peculiar Institution, the Provincial Agricultural Association of Upper Canada.

I think I need not apologise for the length of this letter, for the information will be gladly received by your readers.

Yours truly,

RICHARD L. DENISON.

Dover Court, Toronto, Feb. 1862.

### Maple Sugar.

This is the season for making maple sugar; and this industrial product is of considerable importance in some sections of the country, and might be made of much more value if due attention were paid to the processes of manufacturing and refining. A really excellent and highly palatable description of sugar, almost as white as the best loaf, may be made from the sap of the maple, by the exercise of proper skill and care in these particulars. The following article on "Clarifying," one of a series on the "Importance and best mode of manufacturing maple sugar,"

written by Hon. S. F. Perley, of the State of Maine, for the *Maine Farmer*, will be found to contain some useful suggestions :—

#### CLARIFYING.

When the sediment has well settled, draw off carefully, by a faucet, all the clear syrup from the "settling tub;" leaving the residuum to be diluted with sap, which reduces its specific gravity, when the sediment will be more thoroughly precipitated, and the clear sap, after a few hours, can be drawn off and returned to the boilers, to be included in the next batch; thus making a saving of nearly all the sweet, and rejecting the dirt. The clear syrup may be now poured into the graining kettle; and to a quantity of syrup which will make sixty pounds of sugar, add about one quart of skimmed milk for a clarifier, and thoroughly intermix the two by stirring. The white of eggs well beaten, bullock's blood diluted with water, and other albuminous substances may be used for clarifying; but upon the farm, milk is most easily obtained, is the cheapest, and best. Skimmed milk, if sweet, is equally as good as new milk; for it is the caseine, or curd, acting mechanically by entangling the fine particles of dirt, which the former strainings have not removed, that give it its value as a clarifier. Now place the graining kettle with its contents over a slow fire, and gradually heat the syrup to near the boiling point. This curdles the milk, and as the curd forms it embraces the impurities still remaining; and the curd, by the increasing heat, becomes specifically lighter than the syrup, and eventually floats upon the surface in a thick, somewhat tenacious scum. Care should now be exercised to prevent ebullition, as that would break up the sum, and the action of boiling would carry much of it down to be again mingled with the mass. Now swing it from the fire, and allow it to remain undisturbed an hour, more or less; during which time a great part of the feculencies will attract each other and rise with the scum. The scum is to be carefully removed with a fine skimmer; to draw the syrup from beneath the scum with a syphon, or stop-cock, would be a better way, for then there would be no disturbance, as in the case of using the skimmer; but this would be attended with some inconvenience and expense. Here, again, economy demands that the scum, which has so much sweet in it, should not be cast away; but be placed in a tub and diluted with sap, the allow it to settle a few hours; after which, the sap, much sweetened by the process, may be poured off and returned to the boilers. It is found by considerable experience, that, with the utmost care, the curd and dirt cannot be entirely removed by the skimmer; consequently, resort must be again had to the flannel

strainer. This last straining is usually omitted by sugar-makers, but it is quite important, if a clean, pure, sugar is wanted. A still better process would be to filter the syrup through animal charcoal, (bone black,) as is done in cane sugar refining; for by this process not only the dirt, but all coloring matter, would be removed, which would greatly improve the appearance of the sugar. Bone black, however, cannot be readily obtained in country towns; and the expense and trouble in procuring and using it would hardly be compensated where only a small business is carried on, as is the case in most of the sugar orchards in Maine. If any one desires to experiment in this direction, a filter made of finely pulverized and thoroughly washed wood charcoal will serve as an imperfect substitute for one made of bone black. So late as 1811, wood charcoal was exclusively used in refining syrups; at which time the superior quality of animal charcoal was discovered, and the former soon went out of use. But, by the use of the milk clarifier and the flannel strainer, a very fair sugar for home use can be made; and the ease with which these articles can be procured, and the simplicity of this process of manufacture, commend this method for general adoption.

The first boiling or "turning off," as it is termed, is simply reducing the thin syrup, by boiling, until it is of suitable consistence to be used as a table syrup, like that from refineries; or until it will granulate in sugar. No uniform rule for the consistency of syrup prevails; each maker adopts a standard to suit his own private taste; or else, taking counsel of his cupidity, he refrains from reducing it to a rich, honest, heavy syrup, so that he may have the greater number of gallons to market. Accordingly, much of that offered for sale will pour like water, when it should have the weight and consistency of good W. I. molasses. It should be reduced almost to the graining point, which can only be determined by cooling a small quantity in a saucer or other vessel, and testing it by sight and taste. A first quality syrup will grain a little after straining a few weeks.

To produce sugar, still further boiling is necessary, and the precise point at which the boiling should cease is an item of experience, more easily recognized in practice than described. Several tests are relied upon, some of which are as follows: 1st, where the steam forcing its way up through the foaming mass, on reaching the surface, escapes by bursting its bubble with a slight explosion, similar to that observed upon hasty pudding when nearly cooked: 2d, when a small quantity, say a table spoonful, taken from the kettle and poured hot, upon a compacted snowball, after melting the snow a little, will lay upon

3d, when a drop taken hot from the kettle, on being let fall from the edge of the skimmer or spoon into one inch of cold water will pass directly through the water without mingling with it, and rest upon the bottom in the form of a flattened hemisphere: 4th, when a drop taken upon the finger on being touched by the thumb will draw out a thread from one-fourth to one-half an inch long: and 5th, when a small quantity taken into a saucer or spoon, and thoroughly cooled, will granulate, so that it can be detected by the eye, the taste, or when crushed between the teeth; then it may be removed from the fire for "it is done." These tests, particularly the 3rd and 5th, are useful to beginners as aids in forming a correct judgment; but one long practised in the business seems, intuitively, to recognize the time when the grain will form, and the boiling should cease.

The liquid sugar may now be "turned off" into vessels to cool and granulate. If a fine grain is desired, rapid cooling in shallow pans, with rapid stirring while the crystals are forming will produce the result. If coarse sharp crystals are preferred, leave it undisturbed, in larger quantities until the crystallization is completed. There will be a portion which will not granulate, but will remain as dark coloured molasses filling all the spaces between the crystals of sugar. The quantity of this varies with the season, being greatest near the close; and varies somewhat in different seasons, owing probably to the varying quality of the sap, and the skill used in the process of manufacture.

To obtain a dry sugar, after the granulation is completed, throw the whole into a tub or barrel, prepared for the purpose by boring the bottom with several holes, these holes to be closed until the crystals are well compacted together, say one or two weeks; then remove the plugs and allow the molasses to drain away. The draining will be more perfect, and consequently the sugar of lighter colour, if a wet cloth is spread upon the surface of the sugar, and renewed daily until the draining is completed. The moisture from the cloth, gradually settling down into the sugar, dilutes the molasses, rendering it more liquid, and of course it passes away more thoroughly. A little of the sugar becomes dissolved and carried away by the descending water, but this is not lost, as it mingles with, and becomes a part of a very good molasses. The draining should be done in a warm room, for heat also renders the molasses more liquid and the draining more perfect.

Instead of barrels or tubs with perforated bottoms, inverted pyramidal, or hopper-shaped boxes are sometimes used in draining. These boxes may be 12 or 15 inches square and open at the top, by two inches square and

it without diffusing itself through the ball: closed at the bottom, and three feet long; with a hole at the smaller end for the escape of the molasses; to be suspended like a hopper. These are better than those barrels, for the reason that the quantity of sugar near the bottom, where the drainage is always imperfect, is comparatively small.

Thus we have a crude sugar equal in every respect to the corresponding grade of cane sugar; and superior to it in this, that we know it has been prepared under circumstances far more favourable to cleanliness than exists on Southern plantations, where the operators are driven to their tasks, and care only to avoid the dreaded lash.

It was my intention to offer some suggestions upon the subject of refining, a branch wholly distinct from the manufacture of crude sugar; but the undue length to which the subject has already extended leads me to forbear a further trespass upon your columns. I stop here the more willingly from the fact that the further process of refining, adds nothing to the real value of the sugar, but rather the reverse; for by it weight, and the peculiar maple flavour are, in a measure, sacrificed for an improvement in colour.

### Osier Willow.

To H. C. THOMSON, Esq.,

*Secretary, Board of Agriculture.*

DEAR SIR,—The following paper on the culture and management of the "Osier Willow" has been reprinted in England from the *Rural New Yorker*. It is a subject which every common farmer may easily understand, and there are hundreds of places in Canada well adapted for planting the Osier Willow with success and profit; therefore, without further preface, the following is a copy of the printed paper:—

"Having lately seen several inquiries respecting the Osier Willow and its culture, and being asked almost daily, 'Do you think it will pay?' I have concluded to send you my experience in its cultivation. Three years ago this spring after corn-planting, I set two acres of the French Osiers, placing them in rows three feet apart, at a distance of one foot from each other; the first year I cultivated and hoed the same as corn, and many of the shoots attained the height of four feet. The next spring I cut them, but having no machine for peeling lost the crop, except a few used for sets. Last spring I cut, and commenced peeling by hand, which I found rather an uphill business, and almost resolved to abandon their culture if they must be peeled in this way. About this time a machine was invented for peeling willows. I immediately procured one, which worked to my entire satisfaction, and with it finished peeling my crop, which when ready for market, in-

cluding some sold for sets, a little exceeded a ton. These I shipped to a Commission Agent in New York, and received for them \$110 per ton. This year I have a much heavier crop.—For an experiment I have weighed those cut from 12 stools, which amount to 18 lbs. I have found in peeling and drying they waste nearly one half. The produce of an acre stands thus: 14,520 stools per acre  $\frac{3}{4}$  lb. each, 21,780 lbs.—Ready for market,  $5\frac{1}{2}$  tons, \$110 per ton, \$605, cost of cutting per acre, \$6; cost of peeling per ton, \$7, \$38, binding and taking to market, \$5 $\frac{1}{2}$  per ton, \$27, total, \$72. Deducting expenses, this leaves a profit per acre of \$533.”

“According to directions at the time I planted, I have not cultivated mine since the first year, but think they should be cultivated once every spring, to loosen the soil and keep them free from weeds and grass. I am confident that any one who has suitable ground and will bestow proper cultivation can realize this amount from an acre of willows, perhaps more. After reading these facts I think no one can hesitate to answer the query, will it pay?”

The foregoing computation shews a liberal profit on the experiment. Is it not worthy the consideration of the Board of Agriculture to offer a scale of prizes for the encouragement of the cultivation of the Osier Willow? The season for planting being very convenient, about the same time of planting Indian corn, there is scarcely a farm in Upper Canada without a low swampy plot, which, with open drains, may easily be made fit for its successful cultivation.

The premium should not be less than for one acre, the cultivation to be certified by the President of the County Agricultural Society, where in the plantation is situated.

Your obedient servant,

J. B. MARKS.

Bath, England, Feb. 1862.

### Experiments on Manures.

A short time ago some experiments were published in the *Gardeners' Chronicle* in reference to the beneficial action of coprolites (ground to an impalpable powder) on swedes, in comparison with other manures. The results have, contrary to the opinions of myself and others, induced me to try similar experiments on swedes, the result of which I now lay before your readers. I quite agree with Dr. Voelcker in saying that very little good can be obtained from the result of a single experiment, but often a great deal of harm; and with this view of the case, I intend pursuing the same experiments for several years to come, as I think it is the duty of every one who holds a similar position to myself to do all in their power to connect science with agriculture, and I shall be very glad to join any person in making agricultural experiments who is situated in a different part of England, so as to be able to arrive at more satisfactory conclusions.

The ground experimented on was lately a very old and badly drained piece of pasture to which, after being well drained, salt was applied at the rate of 25 bushels per acre. The field was then ploughed and harrowed in the usual manner, and divided into two parts of  $4\frac{1}{2}$  acres each. On the one half oats were sown, and on the other mangels and swedes drilled in with superphosphate of lime leaving the width of one drill across the field unmanured. Out of this one drill was divided six plots side by side, measuring 4 by 3 yards, each containing eight drills. The plots were manured and sown on the 13th May, 1861, as follows:—

|                                                      | Cwt. per acre. | ton.        |      |   |        |
|------------------------------------------------------|----------------|-------------|------|---|--------|
| No. 1. B. nedust at the rate of $2\frac{1}{2}$ at £8 | 0              | equal to £1 | 0    | 0 | 0      |
| 2. Ground coprolites....                             | 5              | “           | 4    | 0 | “      |
| 3. Unmanured.                                        |                |             |      |   | 1 0 0  |
| 4. Ground bone-ash....                               | 4              | “           | 5    | 0 | “      |
| 5. Superphosphate, ETK's 3                           | “              | 6 10        | “    | “ | 0 19 6 |
| 6. Dissolved coprolites....                          | 3              | “           | 6 10 | “ | 1 19 6 |

The soil was in a fine state of division, the weather dry, and the manures in a finely powdered state, and well mixed with ground ashes before being drilled in with the seed. On the 18th inst. the seed had all appeared above ground and very regular. On June 3rd the plants in each plot were looking well, but those in No. 2 were decidedly the most forward, and those in No. 3 the most backward. Plots 5 and 6 appeared equal throughout the season, and all were treated in the ordinary manner. The amount of phosphate of lime per cent. in the manures used were as follows:—

|                                                                |                |
|----------------------------------------------------------------|----------------|
| In No. 1. Bone dust, 55.35 per cent. phosphate of lime.        |                |
| “ 2. Coprolites, from 60 to 61 per cent. do.                   |                |
| “ 3. Bone ash, 67 per cent. do.                                |                |
| “ 5. Superphosphate, 18.59 soluble and 2.40 insoluble          | } 21.03 total. |
| “ 6. Dissolved coprolites, 21.75 soluble, and 10.35 insoluble, | } 32.10 total. |

On looking at the above we find that

| cwt.                                                                       | lbs.             |                  |
|----------------------------------------------------------------------------|------------------|------------------|
| 2 $\frac{1}{2}$ of bone dust per acre is equal to 165 of phosphate of lime |                  |                  |
| 5 of ground coprolites                                                     | 336              | “                |
| 4 of bone ash                                                              | 800              | “                |
| 3 of sup rphosphate                                                        | 70 $\frac{1}{2}$ | (mostly soluble) |
| 3 of dissolved coprolites                                                  | 77 $\frac{1}{2}$ | “                |

Thus showing the preponderance of insoluble phosphates in Nos. 1, 2, and 3, or the natural manures. All the plants are a great deal too green, and were attacked by mildew just before being pulled and cleaned on the 12th of October. The number and weight of the roots in each plot, with the weight per acre, was as follows:

| Plots. | Manure used.                                   | Rate per acre.  | Weight of roots in plot. | Number of roots in plot. | Average per acre. |
|--------|------------------------------------------------|-----------------|--------------------------|--------------------------|-------------------|
|        |                                                | Cwt.            | lbs.                     |                          | Tons. cwt.        |
| 1      | Bone dust.....                                 | 2 $\frac{1}{2}$ | 114                      | 60                       | 20 3              |
| 2      | Coprolites ground to an impalpable powder..... | 5               | 112                      | 54                       | 20 0              |
| 3      | Unmanured.....                                 | ..              | 102                      | 51                       | 18 0              |
| 4      | Bone ash.....                                  | 4               | 123                      | 52                       | 22 0              |
| 5      | Superphosphate....                             | 3               | 124                      | 56                       | 22 6              |
| 6      | Dissolved coprolites....                       | 3               | 132                      | 58                       | 23 15             |
|        | Average.....                                   | ..              | 118                      | 55                       |                   |

From the above statement it will be plainly

seen that the swedes were most benefitted by the manure which contained the largest amount of phosphate of lime rendered soluble by means of sulphuric acid, although the total amount of bone earth (insoluble phosphates) was less in Nos. 5 and 6 than in Nos. 1 2, and 3, more especially in No. 2. The whole of these experiments were superintended by myself with every possible care, so as to avoid any error. The greatest objection to the above experiment was the small quantity of ground experimented on; therefore next season I intend allotting one-eighth of an acre to each experiment. In conclusion, I may mention that the season was generally fine, not much rain having fallen until after the roots were about two-thirds grown.—E. T. KENSINGTON, F. C. S.—*Gardener's Chronicle*.

### Insects the Past Year.

The following letter of Dr. Fitch to the Directors of the New York State Agricultural Society, and published in the last number of their monthly journal, will be found to contain much useful and interesting matter.—Eds.]

Gentlemen:—The past year has furnished an unusual amount of important material for investigation in the department in which I am occupied. And I had contemplated with much satisfaction, the account of the year's researches which I should have to present in this address at the annual meeting. I will endeavour to hastily sketch the leading topics I had intended to speak of, and if you deem this will be of any interest to the meeting, it may be read as some amends for my non-appearance.

The insects with which my attention was most occupied the past year, were the grain aphid, the army worm and the wheat midge.—And I will aim to notice some of the more important facts that have been thus come to with respect to these insects.

The first of these, the grain aphid, made its advent in a most remarkable manner. That an insect never seen before and not known to be present in our country should suddenly be found everywhere in New England and most of the state of New York, in profuse numbers in every grain field of this wide extent of territory, and literally swarming upon and smothering the crop in many fields, was a phenomenon which probably has no parallel in the annals of science. How it was possible for this insect so suddenly to become thus astonishingly numerous, was a mystery which seemed to most persons to be inexplicable. It is the most prolific of any insect which has ever been observed. I find it commences bearing when it is but three days old, and produces four young daily. Thus the descendants of a single aphid will in twenty days amount to upwards of two millions, each day

increasing their number to almost double what they were the day before. This serves to account for the surprising numbers which we had of this insect.

The aphid was everywhere supposed to be a new insect, and one writer went so far as to name and describe it scientifically, in full confidence that the world had never before known anything like it. My examinations, however, fully assured me that it was identical with a species which has long been known in the grain fields of Europe. And on my announcing this, the erroneous views which one and another were adopting, were speedily abandoned.

Our best European accounts of this insect, however, are very imperfect. They only speak of it as occurring in June and July, whereas I find it is present on the grain the whole year round. And when the grain is but a few inches high, if half a dozen of these insects happen to locate themselves on the same plant, they suck out its juice to such an extent that the plant withers and dies.

As yet I have never been able to find a male of this species. They are all females. This is proved by placing any one supposed to be a male in a vial; next morning too or three young lice are always found in the vial with it. The general habits of insects of this kind are well known. The aphid on the apple and other fruit trees, when cold weather arrives, give birth to males. The sexes then pair, and the female thereupon deposits eggs, which remain through the winter to start these insects again in the following year. I had supposed it would be the same with this aphid on the grain. I thought, when autumn arrived, I should meet with males and find eggs dropped on the blades of the grain. But there were none. The females and their young continued to appear on the grain till the end of the season. They are everywhere on the grain now, buried under the snow, ready to warm into life and activity again when the spring opens. And on grain growing in flower pots, on which I am keeping these insects in full activity through the winter to notice what I can of their habit, no males have yet appeared. When, and under what circumstances this sex will be produced, is a most curious subject, still remaining to be ascertained. It at present looks as though the female and their descendants were prolific permanently, without any intercourse of the sexes.

Last summer, such multitudes of parasites, lady-bugs and other destroyers of this aphid, had become gathered in the grain fields at harvest time, that it seemed as though it would be exterminated by them. But at the end of the season, this insect appeared as common on young rye as I had noticed it at the opening of spring. The present indications, therefore, are that this aphid will be as numerous on the grain the coming summer as it was the past, if the season proves favourable to its increase.

As to the *army worm*, it may be remarked that for almost a century it had been known that in this country was a kind of worm whose habit it was to suddenly appear in particular spots in such immense numbers as to wholly consume the herbage over an extent frequently of several miles, and then abruptly vanish, nothing being seen of it afterwards. Thus it was one of the most singular and almost one of the most formidable and alarming creatures of this class that was known to be in the world. Yet, what kind of worm this was, and what insect produced it, remained wholly unknown down to the present day. Appearing here and there all over the country, the past season, this army worm became the object of the deepest interest; and from Illinois on the one hand and Massachusetts on the other, specimens of the moths bred from these worms were sent to me, for information as to what the name of this insect really was. To these inquiries I was able to give an answer so full and explicit that there has been a general acquiescence in the correctness of my decision on this subject.

With regard to the *wheat midge*, I would observe that, in a lecture before the Society a few years since, I stated that in this country injurious insects were much more numerous than in Europe, occasioning us far greater losses than are there experienced. I was assured of this fact from carefully comparing the statements of foreign authors respecting the depredations of particular insects, with what we know of the same insects here. But I did not suppose it would be possible to show by any more decisive proof that the facts were as I stated. A year ago, however, I received from France a vial filled with insects as they were promiscuously gathered by the net in the wheat fields of a district where the midge was doing much injury. It then occurred to me that, by gathering the insects of our wheat fields here in the same manner, it would furnish materials for a very accurate comparison of the wheat insects of this country with those of Europe. As the result of a comparison thus made, I find that in our wheat fields here, the midge formed 59 per cent. of all the insects on this grain, the past summer; whilst in France, the preceding summer only 7 per cent. of the insects on wheat were of this species. In France, the parasitic destroyers of the midge amounted to 85 per cent.; while in this country, our parasites form only 10 per cent. And after the full investigation of the subject which I have now made, I can state this fact with confidence—we have no parasites in this country that destroy the wheat midge. The insect so common on wheat, and which resembles the European parasites of the midge so closely that, in the New York Natural History, it is described as being one of that species, and in the Ohio Agricultural Reports it is confidently set down as another of them,—I find has nothing to do with the wheat midge, but is the

parasite of an ash gray bug which is common on grain and grass, laying its eggs in the eggs of this bug, and thus destroying them.

In my lecture a year ago, I stated to the Society that the wheat midge had wholly vanished the previous summer; not one of its larvae could I find, on a careful search over an extensive district around me. But the past season this insect appeared in the wheat again, as numerous as usual. This has led us into important changes in our views of the habits of this insect. How was it possible for it to utterly disappear from the wheat one year, and be back in it in swarms the next year? Obviously it must have other places of breeding than in the wheat. And, therefore, if no wheat was grown in this country for a few years, as has often been proposed, it would not starve and kill out this insect. The insect would resort to these other situations, and would sustain itself there, returning into the wheat again as numerous as before, when its cultivation was recommenced. And what could it be that banished this insect from the wheat in 1860, and brought it back again in 1861? The remarkable difference in the weather of these two years furnishes an answer to this question. When the midge fly came out to deposit its eggs in June, 1860, the weather was excessively dry; in 1861, it was very wet and showery. And thus we learn the fact that these flies cannot breathe a dry, warm atmosphere; they are forced to retreat to places where the air is damp and moist. When the uplands, the plowed fields, are parched with drouth, the midge cannot abide in them; it must go to the lowlands along the margins of the streams, where it must remain so long as the drouth continues. Here it must lay its eggs and rear its young, depositing them probably in the grass growing in these situations. And hence we also learn, that if the last half of June is unusually dry, our wheat that year will escape injury from the midge; but if the last half of June is very wet and showery, this crop will be severely devastated. Time forbids my pursuing this subject further.

Yours truly,

ASA FITCH.

(From the Mark Lane Express.)

### Experiments on the Potato Disease.

So multifarious and vague have been the notions of this widely-spreading disease, that it has now become almost habitual, especially in rural districts, to regard a solution of its supposed vagaries as hopeless, and a moderation of its active progress as an absolute impracticability. Now, however, that it has assumed so considerable an importance in a social, moral, medical, economical, and even political point of view, we are impressed with the desirability of divulging the results of a series of investigations on the nature of the disease, the laws it observes, and

the modification of which it, at present, admits. Some 14 or 15 years have elapsed since this intractable disease was by some ill-fated importation brought to our flourishing crops, and from one or more as yet unascertained focuses, swept over this and the sister-isle, dealing uneasiness and sorrow to every abode, from the princely hall to the hutch of the beggar. Speculations innumerable have spent their influence in complicating the matter, and in disheartening many a noble aspirant in the cause; but soon, we hope, we shall be able so to simplify (by accumulation of facts and well authorised inferences) its presumed abstrusities as to render its leading features encouragingly familiar to all. System is essential to the success of the least complex of investigations, and remindful thereof, must the twin sisters Theory and Practice co-operate, otherwise the inductions of the one will be nullified by the more tangible evidence of the other, and all their essays end in irrespondence and confusion; and, with the latter views at heart, we have been actuated, through a series of years, to an attentive study of the potato disease, and have well satisfied ourselves (as botanists have before) that it consists of a fungus, and for the following reasons:—

1st. There exists, without exception, on every diseased leaf, a parasitic fungus, visible as a slight mould, to the unaided eye, and forming a beautiful microscopic object.

2nd. The same fungus is discoverable in the diseased tubers, and in the soil contiguous to the spot on which the latter rotted.

3rd. A like fungus has, we believe, never yet been demonstrated on the healthy haulm, or tubers.

4th. This fungus, when carefully removed from the diseased leaf, and transferred to the substance of the healthy tuber, will (in from four to eight days) *cateris paribus*, originate the specific disease therein at the point of inoculation.

5th. With this fungus in your hand you may infect the haulm of a flourishing crop at pleasure.

6th. All remedies, of any practical value in checking the disease, are reconcilable with its fungoid origin.

7th. All the so-called vagaries of the disease, resulting in its attacking one and not another bed, one part in preference to another of the same bed, now spreading slowly and again swiftly, or even leaving your crop comparatively intact, are readily explained by the laws which regulate fungoid development, and referable to the active or passive migration of the seeds of the fungus (botanical spores) being interfered with by local peculiarities of site; or to their germination being checked or permanently arrested by atmospheric or telluric agencies of limited operation. To popularize a fungus, what is it? A vegetable of the humblest structure, "a miniature mushroom," that in every

instance springs from a parent fungus, often leading an independent existence and obtaining a considerable magnitude, as the meadow mushroom, puff-ball, &c., &c.; but, so disposed to play the parasite, that nearly "every earthly thing" is infested with its fungus; a few—to wit, the human teeth, tongue, throat, and respiratory organs, the "wounds of living men," the helpless caterpillar—may have all organic structure transformed to an exuberant fungus; the wheat, barley, and other cereal crops may be annihilated by their respective funguses; and the mellowing of fruits, their last chemico-vital process, is one preparatory to their decay by the fungus. A fungus differs from all other vegetable structures, in having nearly the whole of its substance composed of reproductive matter, and in effecting its generation by means of minute variously-shaped and tinted bodies, called spores, and which differ from seeds in possessing the capacity of germination from any part of their circumference to which favorable co-existence of heat, air, and moisture, may be presented; whereas a seed can only germinate from one constant point.

We will now pass in brief review the several plans that have been proposed, and had their value tested, for the prevention of the potato disease, viz., the following:—

The method of Mr. Hardy.

do. the C. of Hornsey.

do. The Russian Professor.

do. Mr. Short.

Own methods.

Mr. Hardy's plan is pretty well known in the south of England, and has for its object the destruction of a presumed (but by him undemonstrated) fungus. The tubers are planted in the usual way, or what is best, in ridges, and as soon as the disease appears in the leaves, the haulm is turned down and so retained. Mr. Hardy believed that by so placing the stems you would favour their ablation from the fungus by the rains, and that the parasite, falling on the ground, would, from lack of its wanted ground to play upon, ignominiously perish. The spores alone are washed off by the rains, not the fungus bodily. Potatoes cultivated on the Hardy principle become affected in their stem equally soon as the most neglected; but the tubers suffer, as a rule, numerically less, and, occasionally, considerably less than those uninterfered with. The average proportion of diseased to sound, which we have repeatedly observed, was one of the former to seven of the latter.

The C. of Hornsey aspirant turns the haulm right and left, and places a little soil over the roots, believing that he does, thereby, exclude the rains, and so preserve the tubers from infection; the true explanation of the preserving influence of his plan is found in the fact of the majority of the spores (when put in motion by their own or extraneous force) having in conse-

quence of the horizontal direction of the stems, a greater chance of falling on the bare soil and perishing, than of descending to and about the tubers. This method, when modified by planting the tubers in raised beds as hereafter described, gives most satisfactory results, the tubers being fine, full flavored, and diseased in the ratio of from one in fifteen to one in fifty.

The Russian Professor's principle resolves itself into the conviction of the existence of the disease-generating agent on, in, or about the seed-tubers, and the remedy thereby suggested seemed plausible enough; it was to effect its destruction by artificial heat; viz., by drying the seed tubers in ovens until they were shrunken and wrinkled to almost apparent destruction. Potatoes so treated grew in the ratio of 66 per cent.; their stems were, as a rule, weak, and became infected as soon as any other; whilst the tubers, moderately sound at the getting-up, rapidly rotted at the proportion of 60 per cent.

Mr. Short offered to the public a remedy which, at first sight, seemed to be the most feasible, and of the greatest avail, of any heretofore proposed; it was given as original, and, as far as he was concerned, probably was so; but it had been previously carried out in principle by ourselves, and stigmatized as scarcely worthy of comment. It consists in planting the tubers in ridges; the former six inches apart, the latter thirty; and as soon as the disease is unequivocally established in the haulm or tuber, in turning down the stems, and covering them with six inches thickness of soil. Now such a plan is, *in limine*, laborious, expensive, almost impracticable in some gardens, from scarcity of soil, and, practically, of scarcely any worth, even when all the skill and patience of the most liberal experimenters are thereon bestowed; for if you cover the haulm on the first appearance of the disease in the leaves, you do it at a time when the young tubers are no larger than marbles, or to be more precise, from  $\frac{1}{2}$  to  $\frac{3}{4}$  of an inch in diameter, and though they are absolutely sound, they are of no culinary usefulness; again, if you wait till the disease has advanced further down the stem, till the tubers are tolerably fine, and only just tinted, here and there, with the disease, you find the great heat and moisture evolved by the decaying stems and the fungus thereto adherent, so to favour the spread of the disease, that in one week the number of diseased would reach 1 in 10, and go on rapidly increasing till your potatoes would be diseased in the proportion of 1 to 6. Moreover when the haulm is covered with earth, all true ripening processes at once cease, and Mr. Short was premature in his remarks on the quality of the tubers grown by his method, as they always are, and must necessarily be, smaller, closer, and less flavoured when cooked, than the typically perfect tuber, but comparatively good when the generally inferior quality of the potato crop is considered.

OWN METHODS.—No. 1. When the haulm is diseased about half way down, cut it off close to the ground, rake the soil over the lower portions of the stems, and leave them in the ground one month; this plan is simple, inexpensive, and gives in most seasons a very fair result, e. g., in the best of our yields only three, in another only ten per cent. were diseased; the potatoes, in all cases, were of good size, fairly mealy when cooked, and kept remarkably well.

No. 2. Plant the seed tubers in ridges, and when the disease appears in the haulm turn it right and left, as in the Hornsey method, and place a little earth over the roots; then proceed as in the previous (own method No. 1) and you will still have better results.

No. 3. Decidedly the best method hitherto made public, but one unfortunately almost too tedious and expensive to be carried out except for experiment, or in those gardens in which no expense is of so much consequence as an abundant crop of fine sound potatoes, is the following:—Manure your land in autumn, ridge it afresh on some mild day in the winter, and at the planting season raise therewith a series of beds or ridges 30 inches distant from each other, as high as half of the intermediate soil on each side will admit of, and pointing northeast and south-west; in these let a trench be made eight inches deep, therein the seed tubers placed six inches apart, and the whole covered with soil as fine and light as procurable. (We find the best time for planting potatoes, to be treated on this plan, to be from the middle of March to the 10th or 12th of April); after the haulm is well up, rake the soil up each side of the ridge to the stems, once or twice a month, and when the disease appears, carefully watch its progress, and when the disease appears, carefully watch its progress, and as soon as the main stem is affected, strip off all the leaves and the diseased part of the main stem, carrying them carefully away, and deeply bury them, leaving the defoliated stems to desiccate, or to throw out fresh leaves for one month. On a fine dry day get up the tubers, remove all superfluous dirt therefrom, and when perfectly dry, stow them away for spring use, resting assured that all you find rotten in the spring were tainted and overlooked at the harvest; this method gave in one instance only one, and in another only two and a half per cent. diseased, in both of which cases the tubers were fine, of excellent quality, and kept perfectly sound.

From those and other similar investigations, we may make the following general observations:—

No. 1. The fungus, as a rule, first attacks the stems (but not necessarily so), and then descends to the tubers.

No. 2. The extirpation of the disease from our island is an impossibility, except by a universal concurrence and through a series of years, of preventive measures.

No. 3. Every sort of potato will, under favourable relations, suffer; but, as a rule, the thicker the skin the less prone is the tuber to offer a timely nidus to the spores.

No. 4. Potatoes grown on virgin soil, whether left to their fate or not, will be, numerically, less diseased than those grown on beds that have been, previously, continuously cropped.

No. 5. Land that has lain turf, waste, or copse, for, at the fewest, 30 years, will not grow potatoes proof against the disease—one of the worst crops we ever saw grow on soil that had lain undisturbed turf for 30 years.

No. 6. Diseased stems and tubers should be carried out of the garden, and either buried or burnt.

No. 7. No compost or stytic dressing, *e. g.*, lime, tan, vitriol, or artificial manures, employed in a proportion compatible with luxuriance of growth, will impart to the soil the property of preserving the tubers from infection.

No. 8. Warm, humid weather, with gentle breeze blowing from a variable point, is favourable to the invasion and rapid progress of the disease; whilst cold, dry weather immediately gives an obvious, but usually temporary check, to its advance.

No. 9. Manure used at the time of planting will exert no influence in determining the invasion of the disease in either stem or tuber, but appears slightly to increase its activity after it has declared itself in the tubers.

No. 10. Soils which are well exposed, light, dry, and rich in character, are those that predispose least to the spread of the disease in the tubers; whilst wet soils, especially if shaded, render them much more amenable to its influence.

No. 11. In the present state of science no one can venture to aim at, or propose, an infallible remedy; the best we dare aspire to is to bring the disease by feasible and inexpensive measures within such limits as to be practically of no universal consequence; and with a view of stimulating others to join in the furtherance of so beneficial an object, we sincerely offer these data as bases or aids to their enquiries, hoping, ere long, to substantiate, by conjoint investigations, this desideratum of the Palace and the Many.

E. HOLLAND, M.B., &c., &c.

Stoughton, Sussex, Feb. 11, 1862.

## The Analogy between Plants and Animals

The analogy between plants and animals, familiar as it is, has not yet been appreciated in all its consequences. Every one knows that many of the vital functions are represented by corresponding processes in vegetable physiology; that nutrition, absorption, secretion, respiration, and reproduction, are essential parts, in no metaphorical sense, of the life of flowers and trees.

In some of their habits and properties, especially those connected with the circulation of their sap and the adaptation of their external coating to the exigencies of climate, these simple organisms, which we sometimes rudely term inanimate, display, if we may so say, a discrimination and a self-protecting instinct which have excited the marvel of naturalists. The conditions of health are not, indeed, the same, but similar, in the case of a tree and in the case of an animal; and the violation of these conditions is equally fatal in its effects. Hardier in many respects, in some other trees are far more delicate than animals, and, if their diseases could be ascertained and catalogued, they would probably look almost as numerous and formidable as those which fill medical text-books. Considering the immense value of timber, as well as the keenness of our national taste for ornamental woods, it is certainly strange that the pathology of trees should have been comparatively neglected in this country. The most recondite experiments have been carried on by scientific men to find out the exact proportions in which earth, air, and water contribute to their sustenance, and the ingenuity of landscape gardeners has been exhausted in devising methods for their safe transplantation. But all this time trees have been pining and dying in the prime of life, and strewing the forests with their almost worthless carcasses, and yet no one seems to have bethought himself of ministering to their infirmities, and curing their maladies by timely remedies. Hitherto pruning and lopping have been almost the only operations known to foresters and gardeners; and if the site of a plantation has been selected with due regard to soil and shelter, and its surplus wood periodically thinned out, no other precautions against premature decay have been deemed necessary or practicable.

Our neighbours, the French, though they may be less alive to the beauties of scenery than ourselves, have always shown much skill in economizing the bounty of Nature. Roadside avenues are commoner in France than in England, and the utility of trees is thoroughly appreciated by the peasantry. We are not surprised, that the first step in the medical, or rather the surgical treatment of trees should be taken by a Frenchman. M. Robert, the gentleman to whom we refer, began his labours some twenty years ago, and since that time has undertaken the cure of vast numbers of trees, especially elms, in many parts of France and Belgium. He has taken out a patent for his system, and, if we may judge by the testimonials and honours which he has received from scientific societies and public bodies, his success must have been remarkable. His theory is, that the most inveterate enemies of trees, and especially young trees, are not excessive moisture or unfavorable peculiarities of ground affecting their roots, but certain tribes of xylophagous insects. Of these the chief and most truculent are the scolytes

and the cossus; and the art of curing the ligneous consumption, which has hitherto been considered mortal, consists, according to him, in destroying these insatiable parasites, and fortifying the trunk against their future ravages. His first experiments were made on the large trees bordering the public walks of Paris, and with these he proceeded cautiously and gradually. He scored them in longitudinal sections, hoping in this way to quicken the circulation of sap in the bark between the incisions, at the same time that he laid bare and extirpated the tunnel-shaped nests of numberless tree-consuming insects. Encouraged by the results of this attempt, he ventured to try the effect of stripping trees thus affected of their whole bark—an operation not much less bold in its own way than that of flaying a human being. However, we are told that it succeeded to admiration, that “the scolytes and cossuses found themselves instantaneously annihilated,” and the grubs still in a state of unconsciousness, were buried alive in the process of cicatrization. The trees threw out new layers of “liber,” or inner bark, and even increased in bulk, as we learn from another source, more rapidly than their un mutilated contemporaries. Ever since the discovery was made, the more slashing practice has been universally adopted, and we are told that thousands of elms, already with one foot in the grave, are now convalescent patients or restored to perfect health by the benevolent exertions of M. Robert.

No English trees, so far as we are aware, have yet come under M. Robert's scalpel, and we should be the last to recommend a hasty application of so trenchant a system to the noble clumps and single trees of our public and private parks. But it is certainly worth a trial; for, if there is any truth in the theory, it goes to prove that the hostile scolytes and cossuses are not only responsible for the damage done by themselves, but serve as sappers and miners of other invading insects, besides opening cracks and channels in which the wet lodges and eats into the wood which they generally spare. It is not impossible that further researches will disclose some means of prevention which would be preferable to M. Robert's cure. Meanwhile, however, we have every motive for endeavouring to save the scanty remnant of those woods which once covered Great Britain. As far back as the beginning of this century the neglected state of the Royal forests, and the wastefulness of permitting great oaks to fall, without taking any account of their value or supplying their places with young saplings, were pointed out by Nelson. Since that time we fear that the growth of new plantations has not kept pace with the cutting down of old ones, and that we are becoming more and more dependent on foreign countries for our timber. On free trade principles we have no right to object to this, but so long as it continues to be our interest to grow timber at all, it is surely a dictate of prudence to make it as remunerative as possible by preserving it from

needless decay. Especially in the metropolis, where vegetable shade is so scarce and so grateful, the loss of a piece of foliage is a serious misfortune. How injurious the London atmosphere is to trees has long been known, and it has been remarked as a significant fact that the one which flourishes best in this smoky medium is the plane, which changes its outer bark annually. The elms have no such resource, and whether insects or impeded exhalation be the cause, these characteristic ornaments of our parks have a sickly look. It has been predicted by a prophet of dendrology that elms will be extinct in England before another century has elapsed. The bare idea of such a calamity should rouse the Woods and Forests—for the functions of that department have not expired with its name—from their lethargy on this subject. A generation must pass away before the place of a full-grown tree can be supplied, and the stately verdure of our parks testifies to a forethought which is still rarer now than in the days of our grandfathers. Men too often plant for themselves, and for themselves only, filling up with horse-chestnuts, and other trees of rapid growth, but short-lived beauty, the gaps in ancestral avenues of oak and elm. We lament this selfish short-sightedness when we see its effects on the country seats of individuals; but we have a right to exclaim against it when it affects the interest and pleasure of the nation. We cannot, indeed, blame Mr. Cowper and his predecessors for not having been the first to hail M. Robert's new invention. Now, however, that it has been sanctioned by experience, we are warranted in hoping that no time will be lost in employing some new Evelyn to report upon its application to the forest trees which Englishmen, from the earliest times, have learned to love and almost to reverence.—*Times*.

### Care of Cows before Calving.

The following extract from a Prize Essay on the “Rearing of Calves,” by Thomas Bowick, published in the Journal of the Royal Agricultural Society, (Eng.), is applicable to all latitudes:

“The health and condition of the cow before calving, greatly influence subsequent results. A late milked, lean, raking, ill-cared for beast has oftentimes an easier parturition than those that are better furnished in these respects.—But her after milking has a tale to tell of neglect somewhere; and the scraggy, “set” condition of the calf throughout its after course, often arises more from this cause than from any other. Hence, we would say, dry the cow a *fair time* before calving, and see that she has something better than barley straw to live on, else the calf and its owner will assuredly lose by it. But what is regarded as a fair amount of time for being dry? If a cow brings her first calf when from two

to three years old,—which the majority do, though all will admit that it is too early—we should not care to milk her more than five or six months after calving. By this means she will grow and increase in size and value her second calf. But a cow from the fourth to the eighth year, if in good condition, need not be dry more than six weeks or two months before calving; *i. e.* if fed with a thoroughly liberal hand throughout the year. If more sparingly fed, or if the cow exceeds the latter age, then we should prefer her being dry three months before calving. But, of course, there are exceptions to be met with, which cannot come under any general rule, such as the case of animals whose flow of milk is so strong as to continue almost up to the time when a new lacteal secretion commences."

### How to Feed out Roots.

As root culture is greatly upon the increase in this country, and many are trying their first experiments with them this winter, we will drop a few hints upon their economical use. Nothing is more common than for beginners in the business to confine an animal entirely to the use of roots. They go upon the principle that you cannot have too much a good thing, and give one to three bushels of turnips in a day. The change in diet probably sets the animal to scouring, and turnips are voted a humbug, when the humbug lies altogether in ignorance of the feeder. All animals like a variety of food in their diet, and hay or straw should always form a part of their daily fodder, no matter what else may be added.—This course should be followed, whether we are seeking to make milk or beef, or merely to keep an animal in a thriving condition.—In fattening a bullock, a bushel or so may be given according to size, making out the rest of the feed in hay, with some kind of grain or meal. In feeding milch cows, the same quantity may be given, mixing the sliced roots with the cut hay, at three meals daily. The meal will add more to the quality than to the quantity of the milk. Stock cattle with plenty of hay and roots will not need meal to keep them thriving. A good root cutter is indispensable in feeding out roots.

Then, as to the order in which the various roots should be used up, we always begin with the white, or soft turnips. These grow quickly and remain in their best condition but a few weeks. By the first of January they begin to sprout, and lose something of their value. The ruta bagas and white French turnips keep well through the winter, and may be used at any time; carrots and sugar beets may be used as soon as they are dug. The mangel wurzel needs to undergo a curing

process, and should not be used before February. They are excellent keepers, and will hold on until June. If fed out the first part of the season, they make the bowels loose, and lead to a false estimate of their value.—Analysis shows that the mangel has nearly twice the nutritive matter contained in the Swedish turnip, and experiments in feeding confirm the results of the laboratory. They will yield from fifty to one hundred per cent. more in quantity, under ordinary circumstances, and are much the more profitable root to raise. We find our root crops enlarging from year to year, and that, perhaps, is the best testimony we can give of their value. Our list this year embraces several varieties of the white turnips, rock turnips, and ruta bagas, yellow and white carrots, sugar beets and mangel wurzel.—*American Agriculturist.*

### The Royal Farms.

THE SHAW AND HOME FARMS, WINDSOR.

[The following description of the late lamented Prince Consort's farms at Windsor, from a recent number of the *Agricultural Gazette*, will be read with interest on this side the Atlantic, and will probably afford some useful suggestions of a practical nature to some of our readers. Establishments of a similar description are now getting common on the Home farms of a number of the wealthy land owners of the United Kingdom.—EDS.]

As you walk down the "Long Drive" from the Castle you pass the grounds of Frogmore upon your left, and beyond them on the same side lies the compact homestead and residence known as the Shaw Farm. It has always been a home farm for the supply of the Castle. The late Prince Consort became its tenant in 1849; but up till 1853 it was more directly under the management of the late General Wemyss.—Since then it had been placed in the hands of the late Mr. Wilson, as steward for the Prince Consort; and his successor, Mr. Tait, the present manager, has accordingly been here but a comparatively short time. The manager has altered but little since 1853, when Mr. Wilson, under the Prince's instructions, commenced the formation of the short-horn herd. The principal feature of the farm even still is the admirable equipment of the land with buildings—the exceedingly complete and well arranged farmery at the Shaw, and the perfect arrangement of sheddings, houses, and yards for stock nearer Frogmore, where also the royal dairy has been erected. The herd is, however, growing in numbers and in merit, and though the late Prince Consort had hitherto been an exhibitor of short-horned breeding stock, two or three

had been selected last autumn for a first illustration of his achievements as a short-horned breeder at the great show of 1862.

Though not landlord, as at Barton, the other relations in which he stood gave scope for the illustration of his character as an employer and a neighbour. And one of the most interesting of these illustrations was to be seen in the interest which he took in the welfare of the young men whom he employed. One part of the building at the Shaw farm is an eight-roomed house, where a number of them lodged. It is furnished with a room where they took their meals, and another used as a reading room and for an evening class. The attendance at this winter's evening school was registered, and "copies" and other marks of progress in education were periodically inspected by the Prince, who awarded prizes for attendance and improvement.

The Shaw farm includes 800 acres of land in the Park and elsewhere, 120 acres being arable. It is worked by six pairs of horses—a large number for the land, and more than would be needed were it not for the considerable extra labour connected with roads and estate management. About thirty men are employed, besides other hands, at haymaking and harvest times. The farm stud is wholly Clydesdale, and the Prince had been frequently successful as an exhibitor of them at English Agricultural Society's shows. His last act as the tenant of the Shaw farm about three weeks before his death, was to direct Mr. Tait to nail up over the stalls the premium cards which had been placed over two of his horses at Leeds, and which had lain till then in the farm-house unattached. In anecdotes of this kind, in the frequent walks taken by the Queen and himself round the two farmeries, in his personal inspection of the monthly report presented through Sir C. Phipps, in the instructions given with reference to competition at the national exhibitions, and in his frequent inquiries and conversation about the evening school, the Prince chiefly showed his interest in these arms.

The small quantity of arable land attached to the Shaw farm is managed on the five-field system, two corn crops being taken in succession. There is no lack of manure; the Park supplies immense quantities of fern, which is used as litter in the yards; and great store of yard dung is obtained thus, and from the consumption of hay by the large dairy herd, and that of hay and roots by the young stock. The arable land is accordingly in a high state of cultivation. Forty tons of mangel wurzel per acre are a common crop, and as much as sixty has been obtained. Those lying in store and now in daily use are certainly a remarkably fine sample. The corn is carried home and built in round stacks in a yard near the fixed steam engine. The roots are stored close by.

The buildings are remarkably complete and well arranged. They stand upon a square of

ground, the sides running north and south, east and west, respectively. They consist in the first place of two rows of buildings along the two sides of this square, running north and south. The row upon the eastern side includes cart-shed at either end, two-storied lodging-house and school in the middle, and boxes and farm-horse stables.

The row on the western side includes carpenters' yard and shed, thrashing barn and graneries, steam engine and boiler house, floor for mixing chaff with pulped roots, and piggeries around three sides of a small square, in the midst of which is the food house for their supply. Between these two north and south lines, on the east and on the west sides of the square, there are three rows of buildings, &c., with roadways, between them, and also between their extremities and the two lines already described.

The first row on the northern side includes foreman's house, stable, poultry house, and blacksmiths and carpenters' shops. The second row includes a series of boxes, hamels, (small yards) facing south, and double stalls, with a large root house for the supply of the whole, where Gardner's and Moody's turnip cutters are fixed and worked by strap from a shaft to which the motion is given by a small oscillating one-horse steam-engine standing on the floor, steam being brought for it along a pipe from the thrashing engine boiler house just across the road. The third row occupies nearly half the width of the square, and its whole length between the two lines of buildings at its east and west ends. It is divided midway by a wide shed in which shed-feeding of sheep on sparred floors is adopted, and on either side with sheds at their further ends are two capital yards for young stock. The sheep sheds are now full; they are said to answer well. One hundred and fifty Cheviot wethers are now fattening there. The floor is divided into pens about 9 feet square, holding about six sheep a piece; they receive cut roots and cake, and thrive fast compared with the progress made out of doors. As much as 100 cart-loads of capital solid dung are taken out from beneath them towards spring. The only fault in the arrangement is the imperfect access given to the vaults where it accumulates, and from which it has to be lifted through trap doors in the floor. The place was perfectly sweet, and dry and clean. The buildings are well supplied with corn and cake crushers, millstones, chaff cutters and turnip cutters, all worked by steam power. The granaries are on a third floor over the thrashing barn; the corn is thrashed by Messrs. Collinge & Co's engine, and delivered by travelling cups to the granary bins above, whence it may be sacked and delivered into carts outside by overhanging crane and pulleys from the end of the department.

Wood's combined reaper and mowing machine and other first-class implements of cultivation,

&c., are lying in the sheds. The horses by which they are worked are managed on the Scottish plan; the men working during the full summer day from 6 to 11 and then coming in, and again from 12 to 5—10 hours a day. They are worked hard and well fed, receiving two bushels of corn a week, and a daily feed of beans in addition during seed time and severe work, and hay in effect *ad lib*. One foreman is employed over the men, through whom Mr. Tait gives his orders; himself receiving them when any unusual arrangement is directed through Sir C. Phipps.

A short walk takes you across this to the Home Farm and dairy beyond Frogmore. It is here that the dairy herd is chiefly kept, and that the principle piggeries, those of the white Windsor breed, are placed. The whole accommodation for live stock here is of the most perfect kind.

The principal feature in the arrangement is the magnificent double-rowed cow-house, with its wide central gangway, lofty roof, and roomy arrangement generally. The arrangements for watering and for draining these and all other parts of this farmery are most perfect. There is a complete system of pipage for the supply of water to troughs on one level throughout the building. It is impossible in a short description to enumerate the many clever points of detail by which Mr. Turnbull, the Castle architect, has in these buildings of his designing obviated a great many difficulties, with liabilities to nuisance. The whole of the soakage and drainage of the sheds and yards is conducted to a manure house, whence the liquid, collected in a tank, may be either pumped into water-carts and removed for direct application to the land, or distributed, as it more generally is, over the stall-manure, which is moved at intervals and stored for protection from the weather.

Ready access is given to all the yards and sheds for litter, chiefly fern-leaf mown from the Park and stowed away for its winter purposes, and where pig-food, hay, and roots are stored, easy access is given by gangways to all the feeding houses, stables, cribs, and boxes where the stock are kept.

One of the chief features in these buildings evidently is the ample accommodation for pigs. The comparatively smaller white Windsor breed—from 16 to 20 breeding sows—are kept here. The pure Berkshire—10 to 12 sows—are kept at the other farmery. In both cases there is ample demand for the young stock for breeding purposes. Mr. Tait gives the preference to the Windsor breed, both for fecundity and for precocity. As much as £700 worth of produce has been sold out of the piggeries at the Home Farm alone in a single year.

The dairy stock for which ample accommodation is here provided, is for the most part kept on these premises. Nearly 200 head of stock are now kept—about 80 cows in general of the short-horn breed, besides 10 to 12 Alderneys.

The short-horns, of course are not yet all pure pedigree stock—the pure-bred herd has been growing into existence only during the last eight or ten years.

But since 1855 pure Booth bulls have been used over the whole. Prince Alfred (successful at the North Lincoln Show in 1859, and hired in succession by the late Prince, the Emperor of the French, and Lady Pigott), Fitzclarence, and now Lord Hopewell, have been used over both the pedigree cows and the other stock, and the whole are thus rapidly acquiring a high-bred and common family character.

The pure pedigree herd are descended chiefly from the following cows:—Alix (1853), by Earl of Dublin, bred by Sir C. Knightly, and bought at the Fawsley sale. Rachel, (1850), bred by the Prince Consort, by Goldsmith (10,277), dam Matchless, by Fitzhardinge (8073). Narcissus (1851), bred by Mr. Trotter, of Bishop Middleham, by 3rd Duke of York (10,166), dam Norma by (7996). Coldcream (1851), another Fawsley cow, also got by Earl of Dublin (10,178). Graceful (1852), bred by Mr. Majoribanks, got by Factotum (11,455). Bracelet (1856), bred by the Prince Consort, by Prince Alfred, dam Cowslip, by Bellville; &c; and Sally (1853), bred by the Prince, by Lord Poppington (10,437), also out of Cowslip. Sally was the second prize heifer at the Paris show in 1855. Besides these, a few others more recently introduced and some of shorter pedigree might be included. The cows first named have all been good breeders. Alix and Coldcream have each had five calves and Sally six since 1856. Graceful and Rachel have had six each, and Narcissus five since 1855. They are kept in fair breeding condition. Much of their milk goes to the dairy, and no roots, therefore are given them; they have hay, pasturage, and water. A ready sale at long prices is, of course, obtained for young bulls, and the heifers are taken into the herd and have already begun to add to its number, as by Annette, daughter of Alix; Rosewood and Raby, daughters of Rachel, &c.

The Prince had not been an exhibitor of short-horn stock in this country. He was, however, a successful exhibitor at the International Show at Paris, as already named, and had proposed exhibiting at the International Show this year at Battersea, to which end Prince Arthur, a yearling bull by Fitzclarence (14,552) out of Annette, a daughter of Alix, by Prince Alfred, and two yearling heifers out of Coldcream and Narcissus are being got ready—whether the plan will now be carried out is uncertain. The late Prince was, however, as is well known, a constant exhibitor of other stock at English shows, and a large case full of medals won by him lies on the table in the Queen's apartment at the farm-house. No fewer than 27 silver and 5 gold medals and 6 cups have thus been collected.

Near the Home Farm stands the royal dairy

—a most beautiful sight to see. An apartment some 36 feet by 20 feet in height—the roof supported by pillars—provides marble shelving all around it and marble tables in the midst, on which the white milk dishes stand. The floor, wall, ceiling are all of porcelain—either Minton's tiles as on the floor and roof (the latter presenting an openwork for ventilation), or white porcelain as on walls, or embossed and coloured porcelain as in cornicing and other ornamental parts. The whole is as perfect a combination of form, colour, and lustre as was ever provided for the purpose which it serves, and which is observed in the design throughout. The utensils are of the best common kind—common barrel churn, &c.

Hard by is the aviary and poultry house—a subdivided range of shed and wirework caged-in-yards, in which the various breeds of poultry and kinds of farm-yard fowl are kept.

You regain the Shaw Farm and the residence of Mr. Tait by a walk through the now deserted grounds of Frogmore House, beautiful in the magnificence of its timber trees, the smoothness of its grassy glades and slopes, and the mixture of its groves and mounds and ornamental water; interesting, too, for the mausoleum newly erected in their midst, where lies the body of H. R. H. the late Duchess of Kent; soon, however, to be more sadly interesting still for another resting-place soon to be provided, where the remains of the late Prince Consort will lie in the midst of scenes of quiet beauty, and close by the scenes just visited of intelligent activity, both of which he loved so well.

### Alsike Clover.

*Trifolium hybridum* or Alsike Clover, is a species which appears to a certain extent, to combine the properties of the red and white clovers. It was considered by Linnaeus to be a hybrid, and is cultivated to a considerable extent in the district of Alsike, in Sweden, from whence it derives its name; and was, we believe, first introduced into this country about 1834 or 1835.

It has for the last few years engaged the attention of agriculturists in Scotland and various parts of England to a considerable extent; and its reputation is now so firmly established, that we think it is likely to become much more extensively sown this season than ever it has been before. Its chief advantage consists in its succeeding on land which, from repeated sowings of red and white cloversseed, has become cloversick.

The treatment required for it appears to be very much the same as for other clovers. Our practice and that of our neighbours, on clay land, has been to drill about eight or nine pounds of seed an acre, on barley or wheat, about the first week in April, care being taken that the seed is not deposited too deep in the soil. After harvest, if it has been a growing season, we let our sheep occasionally run over

it, for a month or two, if the weather is fine, our opinion being that the treading of the sheep consolidates the land, and is of great advantage to the Alsike, giving it firm root-hold. About the middle of October, it should be dressed with about six or eight loads of farm-yard dung, as short as can fairly be got. In the spring, it will require the usual bush-harrowing; and when it has made a fair growth, the sheep may again be put on to it, and allowed to remain until the first week in May, if intended for seed: if not, it can be depastured, as other clovers.

We are decidedly of opinion that it should not be fed later than the first week in May, if for seed. Still, we have seen it fed until June; but the advantage appears doubtful, as it shows the harvesting of the seed too late on in the season, and if dry weather sets in there is some difficulty in getting it to make a good start. Last harvest a considerable quantity was left for seed, and the yield is said to be good, the quantity fine, and the price more moderate than it has ever been before. It generally plants well; but last season was an exception, a large breadth of the land sown having missed plant altogether. It has been ploughed up for beans, mainly owing, we consider, to the inferiority of last year's seed. In ordinary seasons, even when thin in the spring, it tillers very much and fills up in a remarkable manner.

When required for mowing, it is left in the same way as red clover, and on land in good fair condition will cut two tons of hay an acre. The feeding qualities of the hay are said to be considerable, but we have seen no analysis of its value compared with ordinary clover hay.

Some difference of opinion is entertained as to the comparative merits of this variety and red clover for the depasturing of sheep; it being affirmed by many growers that sheep will leave any other kind of grass or clover to feed on the Alsike, whilst others consider that its principal merit consists in its succeeding so well on cloversick soils, its perennial habit and fibrous root being so dissimilar to the red or white clover. Where it has been grown, it has invariably been found an excellent preparation for wheat; and we have no doubt it will shortly become sown quite as extensively as either red or white clover, and prove a most valuable acquisition to our artificial grasses. The more it becomes known, the greater will be its cultivation; the high price that the seed has previously borne, and its scarcity, have hitherto prevented its more extended use.—*Mark Lane Express.*

*How to choose a good potato.*—A correspondent of a Scottish paper gives the following rule:—"The finest, mealiest, and most nutritious potatoes are always denser and heavier than the soft and waxy. By taking advantage of this difference in their special gravity, the light and inferior potatoes are made to swim on the surface of a solution of salt, while the heavy and good sink to the bottom."

## Agricultural Intelligence.

### Spring Shows.

We are informed of the following Shows to take place this Spring. We request secretaries of Agricultural Societies to inform us of the date of their exhibitions at as early a date as possible, so as to admit of publication in time to be of use to those interested:—

Fullarton, Logan, and Hibbert Agricultural Society, at Mitchell, April 2.

West Riding of York Agricultural Society, at Weston, April 23.

### Patents of Invention.

BUREAU OF AGRICULTURE AND STATISTICS, }  
Quebec, 20th Feb., 1862. }

His Excellency the Governor General has been pleased to grant Letters Patent of invention for a period of fourteen years from the dates thereof, to the following persons, viz:—

James W. McLaren, of Lowville, in the County of Halton, "An improved feed gear for Straw Cutters."—Dated 26th November, 1861.

Lewis Comer, of the township of Hinchinbrook, in the County of Frontenac, Mechanic, "An improved Bee-Hive."—Dated 29th Nov., 1861.

Thomas Blanton, of Drummondville, in the County of Welland, Carpenter and Joiner, "An improved Broad-Cast Seed Sower and Drag."—Dated 29th November, 1861.

Edwin R. Langs, of the township of Brantford, in the County of Brant, Farmer, "A portable and substantial Fence-post and Fence."—Date 29th November, 1861.

Philip Cady Van Brocklin, of the town of Brantford, in the County of Brant, Iron Founder, "An improved combined Grain Drill, Cultivator, and Horse Hoe."—Dated 29th November, 1861.

Masa Branch Southwick, of Mont St. Hilaire, in the County of Rouville, Manufacturer of Wool and Flax dresser, "A new and useful machine for separating shives, chaff and dust from the Tow of Flax, Hemp, &c., to the be called "Southwick's Tow Cleaner."—Dated 5th Dec., 1861.

Matthew Henry, of the township of Compton, in the County of Compton, Cabinet-maker, "A New Plow, to be called Henry's complete Plow."—Dated 9th December, 1861.

Matthew Henry, of the township of Compton, in the County of Compton, Cabinet-maker, "An improved Fanning Mill."—Dated 9th December, 1861.

James Howell, of the township of Dereham, in the County of Oxford, Moulder, "An Iron Die for moulding and casting Plow Shares."—Dated 16th December, 1861.

William Mahaffy, of the town of Brampton, in the County of Peel, Blacksmith, "An improved Plow."—Dated 16th December, 1861.

## Horticultural.

### Fruit Growers' Association.

We again insert the following questions, and trust that those who have opportunities for observation, will give them their attention.

#### THE FRUIT GROWERS' ASSOCIATION OF UPPER CANADA

Desirous to collect and circulate information relative to the production of the several kinds of fruits in the various parts of the Province, respectfully requests the several Horticultural societies, County and Electoral Division Agricultural societies, Township Agricultural societies, and all gentlemen interested in the subject of fruit culture to cause answers to the following questions to be prepared, and sent to the Secretary, Mr. D. W. Beadle, at St. Catharines, C.W., on or before July 1st, 1862

As the questions are all numbered, the answers may be numbered to correspond, and thus avoid writing down the question intended to be answered.

### QUESTIONS.

#### APPLES.

1. What varieties would you recommend as most suitable to be planted in your locality?
2. What varieties are most profitable for market?
3. What varieties are the most hardy?
4. What varieties have been tried in your neighborhood and found too tender?
5. Are apple trees subject to any disease, or the attacks of any insects in your section, and if so what?

#### SEASON FOR TRASPLANTING.

6. What season has been found most favourable for transplanting, spring or fall?

#### DWARF TREES.

7. Have dwarf apple, pear, or cherry trees, or either of them, been planted in your vicinity, and with what success?

#### PEAR.

8. What varieties of pear would you plant in your section?
9. What varieties are most profitable in your locality for growing fruit for market?
10. Have any varieties been planted and found too tender for your climate, and if so what are they?
11. What varieties do you find to be the most hardy?
12. Are pear trees subject to any disease with you, or to the attack of any insect, and if so what?

#### PLUMS.

13. What varieties of plums succeed best in your section?

14. Have any varieties been tried which proved too tender for your climate, and if so, what?

15. Which varieties would prove most profitable for growing fruit for market?

16. Is the fruit stung by any insect in your locality, thereby causing the fruit to fall prematurely, and if so what insect?

17. Is the tree liable to any disease, or to the attacks of any insects, and if so what?

#### CHERRIES.

18. What varieties of cherries succeed best in your neighbourhood?

19. Have any varieties proved too tender to endure your climate, and if so which are they?

20. What varieties can be profitably planted for marketing the fruit?

21. Are the trees subject to any disease, or to the attacks of any insects, and if so, what?

#### PEACHES.

22. Can the peach tree be grown in your section, and if so, what varieties succeed the best?

#### APRICOTS AND NECTARINES.

23. Can the apricot or nectarine be grown in your section, and if so what varieties succeed the best?

#### QUINCE.

24. Can the quince be grown successfully in your section?

#### STRAWBERRIES.

25. What varieties of strawberry have been found to succeed well in your neighbourhood.

26. What varieties would you plant for market?

#### RASPBERRIES.

27. What varieties of raspberries have been found to succeed best in your locality?

28. What varieties do you recommend to plant in your neighborhood, for growing fruit for market?

#### GOOSEBERRIES.

29. What varieties of gooseberries succeed best in your section?

30. Is the fruit ever covered with mildew?

31. Do you know any varieties that are exempt from mildew in your section?

32. Do you know any means of preventing the mildew, and if so, what?

#### BLACKBERRIES.

33. Has the new Rochelle blackberry been tried in your vicinity, and with what success?

#### CURRENTS.

34. What varieties of red, white, and black currants are most esteemed in your locality?

#### GRAPES.

35. What varieties of grape have been planted in your section?

36. Have any of them proved altogether too tender for your climate, and if so, which?

37. Have any of them proved perfectly hardy and if so, which?

38. Do any of them invariably ripen their fruit well every season, and if so which?

39. Are there any vineyards planted in your neighborhood, and if so with what varieties?

40. Any other information, pertinent to the subject, such as the character of the soil that predominates in orchards of your section; the soil found to be most suitable to the kinds of fruits, &c.

41. Do you know of any seedling fruit of merit in your vicinity? If so please give its history and description; kind, size, color, quality, time of ripening, growth of tree, &c., &c.

Editors of papers throughout the Province are requested to give the above one or two insertions, in order that there may be every opportunity afforded to make the information sought, as full as possible.

### Fruit Culture in Orchard Houses.

*Read by Mr. D. Murray, Nurseryman, Hamilton, before the Hamilton Horticultural Club, on the 6th February, 1862.*

MR. PRESIDENT AND GENTLEMEN,—In my former paper on the orchard house and pot culture, I gave a general view of the system; also, a representation of my hopes of its future; and, as I promised at that time, now make a few remarks on the culture and management, confining myself principally to my own experience.

I stated in my last paper that few trees gave more satisfaction in the orchard house than the peach, the nectarine and vine; this as their being the most valuable fruits. The apricot, the plum, the cherry, the pear, and fig, are also well adapted for pot culture. With many varieties of the smaller fruits, the system adopted is very simple, and may be accomplished by any one who will give the attention. During the summer months we select and mark amongst our maiden plants in the nursery lines the different kinds we want for fall potting. Those so marked are stopped and pinched during the season of their growth; much is gained in this way in giving the trees a good start, whether as pyramid or bush. We also make it a point to pot none but rooted trees of best quality; they are lifted early in the fall, dressed and potted in twelve inch pots; this size I find large enough for any tree for the first few years; when the plants are weak smaller pots may be used. The compost we use is the top spit of rich alluvial pasture land, say of it two-thirds, and one-third of well decomposed manure and leaf mould, all well mixed together, but not sifted, prepared three months previous to use; a good drainage of oyster shells, broken crocks, or charcoal in the bottom of the pots. The roots of the plants being then drained, they are potted; care being taken that the fine roots are all nicely spread out

and the mould well primed about them. When this is done, give a good watering, and set them aside on an outside border, where they may remain until there is appearance of frost; then remove them under cover, lay on their side, and put on a good covering of straw to protect from severe frost during winter. Examine them frequently when in their winter quarters in case of attacks of rats or mice. When spring arrives, uncover and place them in the orchard house; at first, water sparingly, but as vegetation begins to move and the plants commence growth, watering is increased. Ventilate freely when the weather is favourable. Trees are classed as pyramids, dwarfs, or bushes. During the seasons of growth particular attention is paid to the form of the trees. Care must be taken in pinching and stopping, the only means by which a well proportioned tree is got at, and well furnished with fruit spurs. The syringe must be used freely morning and evening, when the trees are not in blossom. When at this stage the trees are subject to be attacked by the aphids; this must be carefully watched, and when they make their appearance, either fumigate or syringe with tobacco water. Some of the young fruit trees will show fruit buds the first season, and even produce fruit, but this must not be permitted, as it is injurious to the future welfare of the tree.

The fruit trees are all top-dressed in fall or early spring, the latter period I prefer in this country, the trees being kept in a dry state all winter exhausts the soil. If this is properly done it is not necessary to change the pots for a number of years. We use the same compost in top-dressing as formerly recommended in potting our trees. Take the old mould out about half way down the pot, taking care not to injure the young rootlets or spongioles that are clustered round the stem. When that is done, we then fill up the space with fresh compost, raming it firmly down with a piece of stick made for the purpose; give a good watering, thoroughly wetting the whole of the ball. The old soil, taken out of the pots, if examined, will be found quite exhausted, and full of small fibrous roots, the greater portion of which will be found either dead or dying; this is a natural consequence, they having done their work.

In pot culture there is an annual provision made of rootlets emanating from the stem as formerly referred to, they get hold of the fresh compost, very soon run through it, and become the principal feeders of the tree. We occasionally use liquid manure for all our trees during the growing season, but only by the hand of an experienced person, otherwise there would be a risk, many of the liquids being very powerful. When it can be obtained, a liquid from sheep-droppings is very excellent, and may be used without danger. When the trees are in blossom air is given freely, but if so at an early period in the season, when the weather will

not permit of it, or of the bees being in to assist in the work of impregnation, we must do it by occasionally giving the stem of the tree a gentle rap with a stick when in bloom, always making choice of a clear day. We find this simple method quite sufficient for the dispersion of the pollen. Those having plenty of time at their command may do this nice piece of work with a camel's hair brush, and do it very effectually by passing the same slightly over the anthers when the pollen is full up. This is a very interesting piece of work. Care must be taken in thinning the fruit in proper time, and not to over-crop the trees. In dry weather continue to give plenty of water, be watchful of the red spider, and all other pests that affect the trees at this season. When the fruit is well advanced give plenty of air both day and night, without which the fruit will not be high in flavour.

For vines, add to the former compost a little crushed bones, giving plenty of water; and as soon as the roots begin to fill the pots give a good watering with liquid manure every third day; attend punctually to stopping the shoots and laterals; stop one joint above the fruit branch, and the laterals two from base on the shoot they spring from.

In conclusion, I beg to state I might have gone more minutely into this subject, but my main object was to convey to you my views as shortly and briefly as possible, trusting you will all encourage the orchard house and pot culture.

## The Poultry Ward.

---

### Something about Hens.

A correspondent of the *N. H. Journal of Agriculture* says: "It is a pleasant recreation to tend and feed a bevy of laying hens. They may be trained to follow the children, and will lay in a box. Egg shells contain lime, and in the winter when the earth is bound with frosts or covered with snow, if lime is not provided they will not lay—or if they do lay the eggs will of necessity, be without shells. Old rubbish lime from chimneys and buildings is proper, and only needs to be broken for them. They will often attempt to swallow pieces as large as a walnut. I have often heard it said buckwheat is the best food for hens; but I doubt it. They will sing over Indian corn with more animation than any other grain. The singing hen will certainly lay eggs, if she finds all things agreeable to her; but the hen is such a prude, as watchful as a weazel, and as fastidious as a hypocrite—she must, she will have secrecy and mystery about her nest—all eyes but her own must be averted—follow her, or watch her, and she will forsake her nest and stop laying. She is best pleased with a box, covered at the top, with a backside aperture for light, and side door by which she can escape unseen. A farmer may

keep one hundred hens in his barn, and allow them free liberty to trample over his hay-mow, set where they please, and lay where they please—and get fewer eggs than one who has a department especially for his fowls, and keeps but half as many, and furnishes them with corn, lime, water and gravel, and who takes care that his hens are not disturbed about their nests.

“Three chalk eggs in a nest are better than a single egg. Large eggs please them. Pullets will commence laying earlier in life when nests and eggs are plenty, and other hens are cackling around them. A dozen fowls, shut up away from the means of obtaining other food, will require something more than a quart of Indian corn a day. I think fifteen bushels a year a fair provision for them; but more or less, let them always have enough by them—and after they have become habituated to finding enough at all times, they take but a few kernels at a time, except just before retiring to roost, when they will fill their crops. But just so sure as their provision comes to them scantily to the last extremity and will stop laying. One dozen fowls, properly tended, will furnish a family with more than 2,000 eggs per year, and 100 full grown chickens. The expense of feeding the dozen fowls will not amount to eighteen bushels of Indian corn. They may be kept as well in cities as in the country, and will do as well shut up the year round as to run at large—and a grated room well lighted, ten by five feet, or larger if you can afford the space, partitioned off from the stable or other outhouse, may be used as a hen-house. In the spring, (the proper season) five or six hens will hatch at the same time, and the 50 or 60 chickens give to one hen. Two hens will take good care of one hundred chickens, until they are able to climb their little stick rosts. They should then be separated from the hens entirely. They will wander less, and do better, away from the parent fowls.—Chickens put in the garden will eat up the May bugs and other destructive insects; but for my own part I much prefer four or five good sized toads; for they are not particular about their food, but will snap up ants and bugs of any kind, and will not, if a good chance offers, refuse the honey bees, but will down them in a hurry. In case of confining fowls in summer, it should be remembered that a ground floor is highly necessary, where they can wallow in the dirt, for they like it as well as the hog likes muck.”

## Veterinary.

### The Progress of Veterinary Science.

The following is a brief report of the introductory lecture, delivered by Mr. Andrew Smith, Veterinary Surgeon to the Board of Agriculture—

at the commencement of his course of lectures on Veterinary Science the present winter:

In commencing a course of study and of systematic enquiry into the details of a profession, it is desirable and interesting to know a little of the early history of such profession. So I will, therefore, first endeavor to give a short outline of the progress of the Veterinary Art. During the last century, the study of the diseases of the lower animals may be said to have begun in a somewhat scientific manner, although we find, previous to that time, even before the Christian era, that celebrated and eminent men practised both human and veterinary medicine. Hippocrates, the most eminent physician of early times, wrote an elaborate work on the horse, and practised the healing art indiscriminately on both man and beast. During the 17th century, numerous treatises on the lower animals and their diseases were brought before the public; a number of them were but of little value, but all tended to direct attention to the diseases of these animals.

In 1761, the first public school for the teaching of the Veterinary art was established at Lyons, under the patronage of the French Government, which institution had for principal, the celebrated Bourgelat, well known to the Medical profession by his writings on Anatomy and Medicine. A regular course of Veterinary Medicine was there taught, under which students acquired an acquaintance with the various forms of disease, and the action of Medicines on domestic animals. A few years later was established the present school at Alfort, near Paris, which is still supported by the Government, and of course is in a most flourishing condition. Subsequently, schools were established in Prussia, Germany, Austria, London, &c.

About the year 1780, St. Bel, a Frenchman, came to London, and made proposals to give lectures on Veterinary Medicine; however, his propositions did not meet with success and he returned to France. Two years afterwards, St. Bel made a second attempt to found a school in London, and this time he was taken notice of by the Agricultural Society of Odeham, and an institution was founded, called the Veterinary College of London, of which St. Bel was principal and Mr. Blain assistant. However St. Bel was not spared to see the fruit of his labors brought to maturity, being suddenly cut off in the midst of his usefulness. After St. Bel's death, it was necessary to appoint a person to fill the vacant chair. Mr. Clarke, of Edinburgh, the King's Farrier for Scotland, was asked to come forward as a candidate, but declined. Mr. Morecroft, an eminent practitioner of London, who had written a treatise on Lameness in the Horse, and who also had studied the Medical Profession, and afterwards learnt the Veterinary Science in France, was next brought forward, and also Mr. Coleman, who had somewhat distinguished himself by some experiments on the

orse. These two gentlemen were elected as joint Professors. A regular course of lectures was delivered, and dissections of the horse carried on. A committee was appointed, consisting of the most distinguished Medical practitioners in London, to examine the pupils, and such pupils as this committee considered to have acquired a sufficient knowledge of the Art were granted Certificates.

The students attending those lectures were granted the privilege of attending the lectures (*gratis*) of the Medical committee, a number of the members composing it being teachers of Medicine. And among the first to whom the Veterinary profession are indebted, was that indefatigable promoter of human medicine—John Hunter. The British Government now voted a sum of money annually for its support, and the rank of Commissioned Officers was granted to such as were appointed to the Army. The East India Company, seeing the beneficial results produced by such appointments, also appointed Veterinary Surgeons to serve with their army in India. After Mr. Coleman's death, Mr. Sewell, formerly assistant professor, was appointed Head Professor. He again was succeeded by Mr. Spooner, who is at present Principal of the Royal Veterinary College, London.

Mr. Simonds has instituted lectures on the Anatomy, Physiology, and Diseases of the Ox, Sheep, and Dog, and Mr. Morton on Chemistry, and Materia Medica. Mr. Morton has now retired, and is succeeded by Mr. R. E. Tuson.

The average attendance of students at the London College is about 100; and a student must attend all the different courses taught at that institution for at least two years before presenting himself for Examination to be granted a Diploma. The Board of Examiners consists of Medical Professors and Practitioners, also a certain number of Veterinary Surgeons, who are affiliated as members of the Board. Of course, numbers of these students do not intend to practice professionally, but are gentlemen and farmers, &c., who, perhaps, attend for one session, and get some insight into the Anatomy and Physiology of the horse, and the nature of the more common diseases affecting Horses and Cattle, and which is of the utmost benefit to them as owners of Stock.

More than forty years ago, Professor Dick, of Edinburgh, commenced to give instruction in Veterinary Medicine, and was recognized by the Highland Agricultural Society of Scotland, and he succeeded in establishing the Edinburgh Veterinary College.

The subject of Veterinary Surgery was first brought permanently under the consideration of the Highland Society of Scotland, at its general meeting in June, 1823, when a committee was appointed and arrangements made with Professor Dick, to deliver a course of lectures. But previous to this, he had given publicly a series of lectures, for several years.

The lectures under the auspices of the Society

were continued in 1824, '25, '26, '27 and '28—during which time the attendance of pupils was limited. The number of students educated at the Edinburgh College, who obtained the Highland Society's Diploma from 1838 to 1844 were 263; the number who obtained the Diploma of the Examining Board, which was appointed by the Royal College of Veterinary Surgeons, and sat at Edinburgh from 1845 to 1848, was 59; and the number who have received the Diploma of the Highland Society, after resuming its examinations from 1848 to 1861, was 333; and in all 655.

The average annual attendance for the two or three past years,—professional, amateur and others, has been over one hundred.

The Board of Examiners consists of Professors in the Edinburgh and Glasgow Universities, Medical practitioners of distinction, and eminent veterinary surgeons from different parts of Britain.

The course of study of the London and Edinburgh Colleges is the same, and consists of the Anatomy and Physiology of the horse, and other domestic animals, and their diseases; Chemistry, Veterinary Materia Medica, and clinical instruction.

The branches taught by the different teachers are, at the London College:—Anatomy, Physiology, and Pathology of the Horse, Prof. Spooner.

Anatomy, Physiology, and Pathology of other domesticated animals, Prof. Simonds.

Descriptive Anatomy, Assistant Prof. Varnell.

Chemistry and Materia Medica, R. E. Tuson.

Anatomical demonstrations, M. W. Pritchard.

Subscribers of Two Guineas per annum, or of Twenty Guineas for life, are entitled to have horses examined as to soundness upon purchase free of any charge; also to have horses treated by the Professors in the infirmary of the College by paying only for their keep, at the rate of one guinea per week, for each horse.

At Edinburgh the classes are as follows:—

Veterinary Medicine and Surgery by Prof. Dick.

Veterinary descriptive Anatomy and Physiology, Mr. Strangway, V. S.

Practical Anatomy, Strangway, V. S.

Chemistry, Veterinary Materia Medica and Pharmacy, Dr. Dalzell.

Physiology, Dr. Young.

Practical Pharmacy and Clinical instruction, Prof. Dick, assisted by Mr. Worthington, V. S.

About four years ago another Veterinary College was commenced in Edinburgh, conducted by Mr. Gamgee, a graduate of the London College, and afterwards an assistant to Professor Dick. The number of students attending the new Veterinary College last season was between 30 and 40, and the course of study is similar to that of the Edinburgh and London Colleges.

Veterinary Students in Britain are rapidly increasing and so is the demand for the services of the Veterinary surgeon. The prospects of the

profession improve with the progress of agricultural pursuits; districts are opening up for the Veterinary practitioner, in which at one time every sick animal was believed to be bewitched, and the tricks of the sorcerer were trusted by credulous and timid people.

Agricultural Literature is improving so much, and farming in the remotest districts is being carried on with such intelligence and enterprise, that there is now profitable employment for Veterinarians, where, certainly, a few years back they could only have expected to starve.

Veterinary science is more appreciated on the Continent of Europe than anywhere else. In France, there are upwards of 3,000 Veterinarians, and the Emperor grants £20,000 to support the French Veterinary Colleges.

Veterinary Science is to the lower animals what Human Medicine is to man; and it must, therefore, be highly beneficial to the lower orders of creation; and it can only be properly attained by a regular course of study. Facts in Medicine can only be discovered by patience and industry. The duly qualified Veterinary practitioner enters upon the duties of his profession with an understanding of Anatomy, Physiology, Nature of Diseases, Chemistry, &c., the same as the Medical practitioner. The Medical man often experiences a difficulty in coming to a correct diagnosis of disease, although he finds a useful guide in conference with his patient. How much more difficult must it be for the Veterinary Surgeon—whose patients are dumb animals, and therefore, he can only judge of the state of their health by physical examination? Hence the greater need of a proper system of training. Even supposing a correct diagnosis cannot be come to, such rational treatment can be adopted by which, upon a second examination, symptoms may be developed by which the precise nature of the disease is detected; and not in that hap hazard method which is practised by many, who attempt to prescribe for the sick and dying, without the least idea of the disease, and the nature of the drug which they are giving, supposing, perhaps, they have inherited medical skill from their ancestors.

The Veterinary practitioners are in a much better position for prosecuting their studies along with the practice of their profession than were the practitioners in the Medical Department, as from their class of patients, they have ample opportunity of prosecuting Physiological and Anatomical studies, and when cases prove fatal, of making post mortem examinations. But to make a post mortem examination, it is necessary to be conversant with the state of the different organs of the animal body when in health. To treat any organ when in a diseased state, it is also essential to know the structure and functions of that organ, or organs, and therefore, in the first place, before undertaking the treatment of diseases of the lower animals, we must study their Anatomy and Physiology.

The Veterinary Surgeon is now convinced that no such sure way lies open to him as the broad and accessible one through the dissecting room. In the Medical profession, the most eminent trace their success to their Anatomical acquirements, and it is owing to this that science so triumphantly exercises the sway over the Medical world at large. By learning Anatomy, we become acquainted with the situation, form, connexion, use, and structure of every part of the body.

Percivall says:—"A Professor of Medicine with a mind unfurnished with a knowledge of Anatomy and Physiology, is precisely in the situation of a mechanic who undertakes to repair a deranged or broken machine without any acquaintance with its mechanism or operations. Both such persons are impostors in their profession, either of them perchance may do good, but there is ever much to be apprehended that they may be working some irreparable mischief. We hear of wonderful cures being performed by persons having no pretensions whatever to medical science, and in this hit or miss manner, it cannot be denied that some very valuable discoveries have been made. Could we, however, but set against these discoveries, excellent as some of them may have turned out to be, a true catalogue of the failures attendant upon the experiments in which they had their origin, we are sorely afraid that the picture would exhibit a complexion, which even the discoverers themselves could not regard without mingled dissatisfaction and remorse.

The Veterinary profession, I am glad to think has progressed equally with other professions, in fact more so than many, as it ranks equal with professions which can boast hundreds of years' standing, and is still improving. I do not mean to say it has reached the same degree of perfection, but it is recognized as a science, and can claim kindred with human medicine. They spring from the same source. To the Agriculturist, and especially to the owners of Stock here in Canada, where qualified Veterinary practitioners are few, a knowledge of the diseases most common to Cattle and Horses is of great advantage, not only as to treatment, but what is better, prevention, especially where there is much quackery carried on. In fact a person ignorant of the nature of disease, had better trust more to nature than to resort to such severe measures as are sometimes used, which instead of relieving only aggravate the disease. Some poor animals receive too much treatment, and I have met with not a few cases of such in Toronio.

In Britain, teaching the farmer how to treat his Stock does not do away with the services of the Veterinary Surgeon. He may help himself when no other means are at hand, but he is not vain enough to think that he can supersede the regular professional man. On Continental Europe and in Britain, the services of the Vet-

erinary Surgeon, I may say, are almost in as much request as the services of the Medical man, and I have no hesitation in saying that such services will be recognized in Canada, for nowhere are the people more intelligent and persevering, and the stock produced in this country will compare favorably with those of any other.

/ From the Scotch Farmer and Horticulturist.

### The Diseases of the Pig.

There are many admirers of the "payer of rents" who bestow as much care and attention to the sty as the lord of the Manor does to his favourite horses. Cleanliness, good food, and regularity in feeding, &c., tend to develop a pigling into the proportions—frightful to the eyes of many—which insure a prize at agricultural shows. We rather admire the cleanly fed pig, not overburdened with fat, which many of the thrifty villagers in England rear, in order to eke out the scanty wages on which a large family has to be kept. Disease now and then appears amongst these animals, but one of the most frequent causes of death and blighting hopes is perhaps the hand of the quack, who, if consulted, should the pig seem out of sorts, may try his hand at giving it a dose of castor-oil, when, as in the process of shearing such an animal, he gets "more noise than wool," as a few loud screams precede the effect of the physic, which far more frequently kills than cures. There is no animal so easily choked as a pig; and we can mention several instances in which young practitioners have poured mixtures fearlessly into the mouth of a screaming pig, but only to feel a dead weight on their hands and see the poor animal stretched lifeless at their feet. It is therefore a rule that tasteless medicine in powder should alone be used for this animal, and the most valuable is tartar emetic. There is no medicine more generally useful in the diseases of the pig, and it is given in some cases in doses sufficiently large to produce vomiting—that is to say, from five to ten grains in a little slop. It is better to give rather a full dose for such a purpose than too small a one, because if the effect is not at once apparent, the drug enters the system and does more harm than good. We do not advise the combination with calomel, but a very worthy rival to antimony in the estimation of some of the best informed veterinarians in the diseases of the pig is the white hellebore in doses of from five to fifteen grains. This drug is an active nauseant readily taken in food, and is regarded as a specific in the frequent and severe attacks of sore throat, which so often present a malignant character in the pig. But we must revert to the administration of tartar emetic in small doses, repeated at short intervals. About a third of a

grain, with ten grains of nitre, given in a little slop several times a day, and stopped when it induces sickness. In severe inflammatory affections, we can recommend this even more than the white hellebore. Although Youatt mentions antimony as an ingredient in many applications for this animal, it is not to be recommended, and we prefer cleaner mixtures than train-oil and sulphur, &c.; but half an ounce of white hellebore, over which a quart of boiling water is poured, constitutes a good lotion for this disease in the pig. White hellebore is, in some animals, a very dangerous poison, but the pig appears to resist its effects in a remarkable manner; and Tabourin, one of the most distinguished authors on veterinary medicines, says that the *poisonous* dose of white hellebore is unknown. As a useful purge for the pig, we may mention a couple of croton beans bruised and mixed with food. Nitre and sulphur are amongst the remedies often of service, and easily administered in food.

The foregoing remarks on medicines to be used for the pig are, we think, called for in agricultural journals, because far too little attention is paid to the kind of medicine, and mode of administration to be adopted, in treating the disorders of the porcine tribe.—Bleeding is the great and universal panacea; but we do not agree with Youatt when he says "this is a most useful and necessary operation, and one which, in many diseases, is of vital importance." It is far less called for in the pig than other animals, and we cannot sufficiently deprecate the plan of docking a bit off the tail, or cutting the ear of the pig whenever he appears a little mopish. Paddy's story imparts a useful lesson. He bled the pig so often by cutting the tail, that in one attack the animal died, because, said Paddy, "he had no more tail to cut, and had to wait for it to grow again." The amount of blood lost by the tail is trifling, and the operation may be justly condemned as useless.

To see a sick pig is in the estimation of some even more rare than seeing a dead donkey, and it may be deemed a waste of time to devote valuable space to the consideration of the diseases of the animal. But there are those whose experience would indicate a heavy mortality, and it is undoubtedly the fact that very dangerous contagious fevers, destructive parasitic disorders, and other maladies are to be witnessed in well-stocked sties.

Just as all diseases of the dog are called "distemper," many of those of the horse are termed influenza, and a large number in cattle are at once declared to be pleuro-pneumonia, so are all the diseases of the pig known by the absurd name of measles. We say absurd because there is no similarity at all between the many forms of disease termed measles in the pig and the same affection as seen in man.

We could cite several instances of sudden deaths in the pig which veterinarians have declared to be due to measles, whereas this name has been applied by the better informed exclusively to that speckled condition of the skin due to hydatids beneath it, and which hydatids—all members of the genus *Cysticercus*—pervade the soft tissues in the body, and if swallowed uncooked, produce tape-worm in man. This fact alone proves the importance of knowing more than is usually done regarding pig diseases.

We have recently discussed the injurious effect of overfeeding horses, sheep and cattle. We can furnish an admirable illustration of the *plethoric* state in pigs. Our readers must not forget that *plethora* signifies that condition of the system when the blood is in excess both as to quantity and richness; but chiefly the latter. A brewer in Edinburgh kept a few young pigs to supply himself with choice morsels of pork and ham. During the past winter on a showery day, the pigs were declared to be trembling, foaming, and fuming. All, without exception, manifested symptoms of disturbance, varying in severity, but the best were most dangerously ill. Three died in rapid succession, and advice was sought. The poor pigs had received an extra rich supply of food, containing a heavier proportion of good barley than they were accustomed to; their high condition would not admit of such an addition to their supply, and they were thus destroyed. Our readers will perhaps remember the instance before recorded of high fed cattle being killed by a too liberal supply of the best oil-cake. It is a parallel case to the one here mentioned among the pigs.

It is evident that moderation in feeding, and perhaps an occasional dose of medicine, are as essential for the health of the pig as for that of other domestic quadrupeds.

**BOTS IN HORSES.**—The editor of the *Indiana Farmer* says he publishes a receipt for the third time, by special request of those who have used it with perfect success. It is as follows:—

"Take a tablespoonful, a little heaped, of alum, and the same quantity of copperas, pulverize them fine and put them into a pint of vinegar. Pour it down the horse's throat. It will generally afford relief in five or ten minutes."

### Miscellaneous.

#### Historical and Scientific Facts about Petroleum.

Within the last three years there has sprung up in this country an important and extensive branch of industry—the refining of petroleum,

or, as it is sometimes called, a mineral oil. This is already a staple article, and its use as an illuminator, is becoming every day more extended. When properly manufactured it is not explosive, it affords a brilliant flame, it can be furnished at a moderate price, and, moreover, its sources of supply in this country are abundant. The subject is one of so much general interest that we are induced to publish the following interesting article concerning this substance, which was sent to us by a member of the Chemical Society of Schenectady, N. Y.:—

Petroleum is not of constant composition, but is a variable mixture of numerous liquid hydro-carbons, as benzole, naphtha, kerosolene, &c., with paraffine, naphthaline, and asphaltum, solid hydro-carbons. It is of a very dark green colour, and in density varies from a thin fluid, lighter than water, to a thick viscous liquid, heavier than water. The lighter qualities yield the larger proportion of burning oil.

The evidence of the most ancient occurrence of petroleum is among the ruins of Ninevah, whose existence dates back more than two thousand years before the Christian era. In the construction of this city, an asphaltic mortar was extensively employed, the asphaltum being obtained by the evaporation of petroleum.

A later mention is found in the accounts of Babylon, whose walls were cemented with asphaltum, which was poured, in a melted state, between the blocks of stone, and an indestructible mortar thus secured. This asphaltum was procured from the fountains of Is, which were about one hundred and twenty miles above Babylon, on the Euphrates. Together with saline and sulphurous water, it issued from a rock and was conducted into large pits. The oily matter was then skimmed off and solidified by atmospheric evaporation. These springs, from the abundance of their products, attracted the attention of Alexander, Trejan and Julian, and even at the present time, asphaltum procured from them is sold in the neighbouring villages of Hits.

From time immemorial asphaltum has been found on the shores of the Dead Sea, and this is one of the most remarkable localities for it. This sea, as is well known, is of supposed volcanic origin; and is the probable site of the ancient cities of Sodom and Gomorrah. Its surface is thirteen hundred feet below the surface of the ocean, and it has been fathomed to the depth of two thousand feet. In several places no bottom has been reached, and, owing to internal convulsions, the depth changes from time to time. The water is very dense, holding in solution twenty-five per cent. of solid matter, of which seven per cent. is salt. The bituminous substance is up-thrown from below and towards the centre of the sea it is found in a liquid state, like petroleum; but it is probably solidified by evaporation, as it appears upon the shores in hard compact masses. The explanation of this phenomenon is that a con-

nection between the sea and some internal volcano exists, whence this substance is ejected.

At the vicinity of the Caspian, the Bakoo springs have yielded large quantities of oil, and are widely celebrated. Some of the Persian wells have furnished fifteen hundred barrels a day, and throughout this region this material, under the name of Naphtha, is very generally burnt for its light.

At Rangoon, in Burmah, petroleum has been obtained for many years, and at this time there are over five hundred wells, which annually afford four hundred thousand hogsheads. The oil occurs in a stratum of blue clay; wells about sixty feet deep are dug, into which the petroleum oozes. This is sometimes used in its natural state, but more frequently it is first purified by distillation with steam. The raw material is also mixed with earth and used as fuel.

In Europe there are a few abundant springs. On one of the Ionian Islands there is an oil fountain which has flowed for over two thousand years: and the oracular fires of ancient Greece have been attributed to similar sources. Oil springs also occur in Bavaria, in the Grand Duchy of Modena, at Neufchatel, at Clermont and Gabian in France, and near Amiano in Italy. Petroleum procured from the last named locality is used for lighting the city of Genoa, but elsewhere in Europe it is not employed, to any extent, as an illuminator.

On this side of the ocean there is an enormous quantity of this substance. Upon the Island of Trinidad, one of the West Indies, at a distance of three-fourths of a mile from the sea, is a lake of asphaltum three miles in circumference. Near the banks the asphaltum is hard and cold, but as you approach the centre the softness and the temperature increase, until finally it is liquid and boiling. From the bubbling mass proceeds a strong, sulphurous odour, which is perceptible at a distance of ten miles. Between the banks of the lake and the shore of the island is an elevated tract of land, covered with hardened asphaltum, upon which vegetation flourishes. The explanation put forward in connection with the Dead Sea, is equally applicable in this case.

Upon others of the West Indies petroleum has been obtained, as well as at several places in Central and South America; but it is in the northern portion of this continent that the abundant reservoirs of this substance are located; and it seems truly wonderful that their extent and richness should not have been discovered at an earlier period. For many years the Seneca Indians collected petroleum, and, under the name of Seneca oil, sold it as a remedy for rheumatic complaints. At numerous places in the Middle States it was found in salt borings, and was collected and burnt by the farmers, but it was not till August, 1859, that it was obtained in noticeable quantities. At this time oil was "struck" upon Oil Creek, Venango County, Pennsylvania,

by sinking an Artesian well to the depth of seventy feet, and for many weeks a thousand gallons a day were pumped from it. The news of this discovery spread far and wide, and gave rise to an "oil fever." Thousands flocked to this vicinity in the hope of making their fortune. Before the close of 1860 there had been over a thousand wells bored, many of which were productive, but a large proportion returned nothing. Some of the adventurers have been very successful, and have made large amounts of money; but, as in all commercial "fevers," a large number of persons have been utterly impoverished by their speculations. The mere sinking a well by no means insures a bountiful supply of oil. The petroleum is stored in fissures formed by the upheaving of the earth's crust by volcanic action; and these fissures are perpendicular rather than horizontal in tendency, as is proved by the fact that at wells but a few rods apart, the oil is "struck" at very different depths. The lowest parts of the fissures contain water, above which is oil, while in the highest portion there is a quantity of gas. If, therefore, the well strikes the fissure at the lowest part, the water will be forced up by the pressure of the supernatant oil, and gas. Persons ignorant of the formation sink a well at random, and perhaps strike a fissure; but obtaining nothing but water, they abandon the spot as worthless, whereas after removing the water by pumping, a large quantity of oil might be obtained.

In some localities in Ohio, as is the case in Burmah, the ground is saturated with the oil, and wells several feet in diameter are dug, into which the oil oozes. Porous limestone, containing petroleum, is found in some sections of the West, and has been subjected to distillation with profitable results.

In regard to the origin of petroleum, scientific authorities differ; but the theory most generally favoured is, that it is the product of the slow distillation, at low temperatures, of organic matter in the interior of the earth; the vapours being condensed in the previously-mentioned fissures and the surrounding soil. The lake of Trinidad and the bituminous matter of the Dead Sea may also be referred to a similar source. But for how many centuries must this operation have been going on to have effected such enormous results?

Of the many uses to which petroleum and its derivatives are applied, that of illumination is the most important; and the process of refining is extremely simple. The crude material is put into a large iron retort, connected with a coil of iron pipes, surrounded by cold water, called the condenser. Heat is applied to the retort, and from the open extremity of the condenser, a light coloured liquid of strong odour soon flows. This is naphtha, and is very volatile and very explosive. Some refiners mix it with the burning oil, and numerous accidents have resulted from such mer-

enary indiscretion. It is usually run into a separate tank. After the naphtha has passed over, the oil used for illumination distills off. Steam is now forced into the retort and the heavy lubricating oil driven over. There now remains a black, oily, tarry matter, sometimes used to grease heavy machinery, and a black coke, employed as fuel. There are, therefore, five substances separated in this operation, but only the first three are of any economic importance.

The naphtha is used as a substitute for turpentine in paints, or by repeated distillations the benzole is separated from it and employed to remove spots from fabrics. This, however, is rather a drug in the hands of the refiner.

The burning oil, as it comes from the retort, is of a yellow colour, and in order to remove this, it is placed in a large lead-lined cistern, and agitated with about ten per cent. of sulphuric acid. After the acid and impurities have subsided the oil is drawn off into another tank and agitated with four per cent. of soda lye. This last operation is to remove any acid remaining with the oil, and also to extract the residue of the colouring matter. In fact it is sometimes employed alone and a very good oil obtained. The oil is now agitated with water to remove the soda lye, and is then ready for consumption. The colourless oil is by no means the most economical, but on the contrary more light is obtained from the yellow article.

The heavy oil is cooled down to 30 degrees Fah. when the paraffine crystallizes out, and is separated from the oil by pressing. It is further purified by another pressing and by alternate agitation, in a melted state, with sulphuric acid and soda lye. It is then moulded into candles. It is a curious fact that the composition of paraffine and good coal gas is exactly the same.

In Egypt a substance derived from petroleum was used in embalming bodies; and in Persia and the neighbouring countries asphaltum is used to cover the roofs of the houses and to coat the boats. In France asphaltic pavements have been successful in several cities, and for the protection of stone no material is better adapted. Mixed with grease the Trinidad asphaltum is applied to the sides of vessels, to prevent the borings of the teredo, and with quicklime it affords an excellent disinfectant. Among the products of the distillation of petroleum are naphthaline and kerosolene. The former is the substance from which is obtained aniline, the base of the beautiful colours mauve, magenta, and solferino. The latter has been proposed as a substitute for chloroform and ether. Many other substances have been separated, but as yet none of them have been applied. As this is comparatively a new field many discoveries may be confidently expected in the course of a few years.—*Scientific American*.

## Great Oil Spring.

The somewhat celebrated Mr. Shaw of Oil Springs village, is not destined to share alone the honour and profits of that remarkable locality. Yesterday, Tuesday, the 18th inst., another person, Mr. Bradley by name, having been boring at a spot situated about two hundred yards distant from Mr. Shaw's spring and having reached to about an equal depth in the rock as he attained, was rewarded for his exertions by an up-flow of oil to an extent of 100 gallons per minute. There being no means of saving it, it has overflowed the land, as was the case with Shaw's spring, when it first flew up, and a pitiable waste is going on. Black Creek has become literally a sewer for oil, and its waters are covered over to a depth of fully three inches with the dark green fluid, the wastes from the surrounding wells and springs. The last success of Mr. Bradley was quickly known to the men in the district, each of whom left his well and proceeded to witness the new wonder. They saw in astonishment, and returned to their respective lots, each determined to bore deeper and deeper until the source of the supply should be tapped, and each possess in his own right not an oil well merely, but a veritable oil spring, which should bubble up spontaneously to the surface.

The fact is, the whole district is impregnated with oil. The soil is made viscid by it. A piece of earth adheres to your boot, and you become at once odoriferous and offensive. Oil is every where. One tastes it in the beer, and even whiskey fails to kill it out. The flavor is detected in the bread. You eat bacon, but you taste oil. You smell it and taste it in the air, and hold your nose to lessen its ungracious influence upon the olfactories. You go to bed but the sheets are oily. You open a door, and your hand which has touched the handle has caught the contagion. You proceed to wash, and find a film of oil upon the water, and as you wipe your face, the skin is imbued by an oleagenous deposit from the towel. Oildom asserts its sway, and Oil is King?

But the means of transporting the immense supply of oil is altogether inadequate to the necessity of the case. Lumbering barrels at \$2 each are behind the age, even if they were to be had in sufficient numbers, and it is imperative, therefore, that some, new mode of carrying away the precious unctuous flow should be adopted. The plan now proposed is, to lay down a five inch iron pipe to Sarnia, and cause the oil to flow into a common reservoir there, and from thence to be filled into iron tanks, and so conveyed to the seaboard. No vessels or implements once used in this traffic are available for other purposes, as the odour from the oil is so pungent and persistent, that it spreads itself into every cranny of a ship in which any

large quantity of it may be conveyed. Not long since a few barrels of oil were taken across the Atlantic in a large grain vessel, and the result was thus the great portion of the grain was spoiled. It is thought, then to press into the service, as a kind of retributive justice, the old whale ships, for if the supply of the oil continues, the whales will be left to enjoy their monstrous gambols undisturbed by the harpoon. To pass from the pursuit of the whale to be the carriers of ready-made oil, would not be difficult, though decidedly unromantic.

If some such plan were adopted, this natural oil well, if the supply continues, become one of the most useful and economical substances known, and will find its way into hundreds of uses. Already such experiments have been made as to convey the conviction that gas of a superior kind can be made from it at sixty cents per thousand feet, while for the ordinary purposes of light, the supply being so plentiful and apparently unlimited, the illuminating fluid now sold must fall in price to such an extent as to make artificial light, to use a vulgar phrase "as cheap as daylight." From whatever point this subject is viewed, whether as regards the origin of the oil; its supply; the extent of country under which it is found: the uses to which it can be applied; the revolution it is making in the cost of artificial light, in each and all it is most wonderful, and we question if a more interesting sight than that of the Canadian Oil Springs at Wyoming exists in any part of the world.—*London Free Press*.

**THE LAND OF PARADOX.**—The quicksilver, I find, will sometimes disappear, like the water in the pipe of the Great Geyser, and even then the weather will be tolerable. But that is as it should be, and quite in keeping with the regions of paradox which we are approaching, where the magnet forgets its affection for the pole; where as many as nine suns have been seen in winter without affording the warmth of one; where the favorite time for thunder and lightning is mid-winter; where a river of to-day becomes a mere fountain of to-morrow, and *vice versa*, where islands rise out of the ocean, and sink down again, as if nothing had happened; where tiny clouds, according to the testimony of voracious travellers, at times swoop down like falcons on the head of the wayfarer and disorder his brains. A land out of which is dug that mysterious selturbrand which geologists have been adding their brains to explain the origin of, but in vain; a land where the people get their wood from the ocean and where ocean cod are taken in inland lakes; where, if you find a stalactite, it is due to fire instead of water; where dark ducks with white rings round their eyes swim in the boiling Hyers—and where ice and fire are often on the best terms with each other. So that fine weather and a low glass are really quite the correct thing.—*The Oronian in Iceland*.

**A PLACE WHERE NO WINTER IS.**—The exceptional warmth of the winter climate of Mentone, even for the Riviera, is proved by the presence of groves of large, healthy lemon trees, which occupy the sheltered ravines and warmer hill-sides, wherever water can be obtained, constant irrigation, summer and winter, being necessary for their cultivation. They are, indeed, much more numerous than the orange trees, although many fine plantations of the latter are found throughout the district. Orange trees can bear without injury several degrees of frost, whereas one degree destroys the fruit of the lemon tree, and two or three degrees destroy the tree itself. On one side of the second bay, near the Port St. Louis, the warmest and most sheltered region of Mentone, the side of the mountain is partially covered with lemon trees, which ascend on terraces to a considerable height above the sea. In these "warm terraces" winter certainly may be said not to exist. Throughout its entire duration insect life is abundant, and the swallows consequently never migrate. They are constantly seen arching among the rocks. The harebell, the red valerian, violets, and our own pretty veronica, flower in December and January in this favoured spot, long before they appear elsewhere. The lemons produced at Mentone are known throughout northern Europe, and fetch a high price in the market. The lemon tree at Mentone flowers all the year round, never resting, and bears four distinct fruit crops. Its existence in groves of large trees, from twenty to thirty or more years old, without artificial protection, and its profitable cultivation throughout the year, prove that there must have been freedom from frost for many years. I was told, however, that about twenty-five years ago nearly all the lemon trees in the country were destroyed in one night, which may account for no very old trees being seen.—*Mentone and the Riviera as a Winter Climate*; by J.H. Bennet, M.D.

**THE MOTH'S WING.**—Touch with a camel's-hair brush any part of the wing, so as to remove scales, dab the brush on a pane of glass, put it under the microscope, and then see how each particle of the almost imperceptible and impalpable coloured dust which clothes the wings becomes manifest as an elegantly formed scale, sculptured with designs of singular beauty and regularity, formed of at least two, if not three separate membranes, and waved, toothed, or fringed at the extremity, according to its position on the wing. Just consider how many hundreds of thousands of these scales are needed to cover a surface so great, and the inconceivable care which is required, not only in making them, but in setting them in rows more regular than the slates on a house-top, each overlapping the other, and arranged so as to defend the delicate membrane of the wing from moisture. You cannot wet a moth's wing with water, for it runs off in drops as if the wings were covered with oil.—*St. James's Magazine*.

### The Poet Laureate and the Late Prince Consort.

A new edition of the *Idylls of the King* contains the following dedication:—

These to his memory—since he held them dear,  
Perchance as finding there, unconsciously,  
Some image of himself—I dedicate,  
I dedicate, I consecrate, with tears.  
These Idylls,

And, indeed, he seems to me  
Scare any other than my own ideal knight,  
Who revered his conscience as his king;  
Whose glory was redressing human wrong;  
Who spake no slander—no, nor listened to it;  
Who loved one only; and who claved to her—  
Her, over all whose realms to their last isle,  
Commingled with the gloom of eminent war,  
The shadow of his loss moved like eclipse,  
Darkening the world. We have lost him; he is gone;

We know him now: all narrow jealousies  
Are silent; and we see him as he moved,  
How, modest, kindly, all-accomplished, wise,  
With what sublime repression of himself,  
And in what limits, and how tenderly—  
Not swaying to this faction or to that;  
Not making his high place the lawless perch  
Of wing'd ambitions, nor a vantage-ground  
For pleasure; but, through all this tract of years,  
Wearing the white flower of a blameless life,  
Before a thousand peering littlenesses,  
In that fierce light which beats upon a throne,  
And blackens every blot: for where is he  
Who dares foreshadow for an only son  
A lovelier life, a more unstain'd than his  
Or how should England, dreaming of his sons,  
Hope more for these than some inheritance  
Of such a life, a heart, a mind as thine,  
Thou noble Father of her Kings to be—  
Laborious for her people and her poor,  
Voice in the rich dawn of an ampler day,  
Far-sighted summoner of war and waste  
To fruitful strifes, and rivalries of peace,  
Sweet nature gilded by the gracious gleam  
Of letters, dear to Science, dear to Art,  
Dear to thy land and ours—a Prince indeed,  
Beyond all titles, and a household name,  
Hereafter, through all times, Albert the Good?

Break not, O woman's heart, but still endure;  
Break not, for thou art Royal, but endure,  
Remembering all the beauty of that star  
Which shone so close beside thee; that ye made  
One light together, but has past and left  
The Crown a lonely splendor.

May all love

His love, unseen but felt, o'ershadow thee;  
The love of all thy sons encompass thee,  
The love of all thy daughters cherish thee,  
The love of all thy people comfort thee,  
Till God's love set thee at his side again.

VALUE OF A DEAD HORSE IN LONDON.—Hair from 8d. to 1s.: used for haircloth mattresses: in crushing seed in oil mills. Hide and tendons, 8s.: leather, glue, gelatine. Flesh, £1 8s.: meat for men, dogs, and poultry. Heart and tongue: a mystery. Intestines: covering sausages and the like. Fat, 3s 4d.: used for lamps after distilling. Bones, 4s. 6d. per cwt.: knife handles, phosphorous, and superphosphate of lime. Hoofs, 8s. to 10s.: buttons and gelatine. Shoes 2s. to 3s.: old iron. Total value, from £2 17s. 6d. to £3 4s. 10d.

### Editorial Notices, &c.

PURE SHORT HORN STOCK.—We beg leave to direct the attention of breeders of Short Horned Cattle, to the advertisement in another place of pure bred cattle for sale by Dr. Phillips, of Prescott, C. W., the stock being at present placed for keeping on the opposite side of the river, near Ogdensburgh, N. Y. These cattle were exhibited at the London Provincial Show last September, where they gained several premiums, and although from their recent passage across the Atlantic, and rather poor kept since arrival, they were not in so high condition as they should have been to show to advantage, they yet attracted the attention of connoisseurs by their good points and evident high breeding. The cattle are from some of the best herds in the old country, and have all good herd book pedigrees. We understand that private reason, have induced Dr. Phillips to return to the old country to reside, instead of settling permanently in Upper Canada, as was his intention when he imported his cattle, but we trust that the stock may remain in the country for the improvement of our native herd.

### Imported Thorough Bred Cattle FOR SALE.

THE SUBSCRIBER OFFERS FOR SALE, the whole of his lately imported herd of improved Short horns. Full pedigree for each, authenticated by reference to Coates' English Herd Book.

G. W. PHILLIPS,

Ogdensburgh, N. Y.

VOL. XIV.

TORONTO, MARCH 16, 1862.

No. 6.

The Cultivation and Preparation of Flax.

Flax-culture is a subject that has already received attention in the pages of this Journal, particularly in the volumes of the last and preceding years. As the matter is daily acquiring more importance in Canada, and has already assumed a practical character in more than one locality, we shall proceed, in accordance with instructions received from the Board of Agriculture, at its last meeting, to throw together some plain and practical observations on the most approved methods of the culture and treatment of flax; to which both the soil and climate of Canada are generally well adapted.

Flax of one kind or another has been cultivated and employed for textile purposes from remote antiquity. It is several times mentioned in the Bible. The Greeks were well acquainted with the uses of the plant; and most of the writers on Roman husbandry distinctly refer to it, sometimes with considerable detail, particularly Pliny, who treats with great minuteness of its culture, and subsequent preparation. After the fall of the Roman Empire, but little can be learnt respecting it till the twelfth century, when we learn from documents that have come down to us, that flax has been regularly cultivated both in the British Islands, and the continent of Europe. Much curious legislation took place in reference to the culture and manufacture of

this plant during several centuries, some of which would be both amusing and suggestive to our readers, if space would permit us to descend to particulars.

There are several species of flax, some of which are to be found either cultivated or indigenous in countries in each of the four quarters of the world; and also in Australia and New Zealand. Most of these possess fibres more or less suitable for textile purposes; but only a few have attained to any agricultural or commercial importance. The only species that can be said to have any claim on the farmer's attention for general cultivation, is the *Linum usita tissinum*, or common flax; "which is an annual plant, with delicate branching, round stem, from 18 to 24 inches, covered thinly with narrow glaucous, thin ribbed leaves, and bearing at the ends, pale, blue, shining flowers. The flower heads possess four, or more commonly five sepals; the petals are always equal in number with the sepals; the stamens are also equal in number, and alternated with them. The flowers are succeeded by a seed-pod, or ovary, agriculturally known as the "boll" or "capsule," with ten divisions, or rather five perfect cells, which are again separated by an imperfect partition, extending from its outward wall. In each of these cells is found a single seed, of a flattened oval shape, of a more or less dark brown colour, mucilaginous to the taste, and containing a large proportion of a brown-

ish yellow oil, possessing the peculiar though slight smell characterizing linseed oil. This oil is readily obtained by pressure from the seed; the residuum being the well known feeding substance termed 'linseed cake.'

*Soils suited to flax.*—This plant may be said to have a wide range both of soil and climate, and is therefore well adapted to an extended course of husbandry in most of the countries occupying, at least, the temperate zone. It can be grown by judicious culture on sands, gravels, marls, and clays; alluvial or swampy lands when thoroughly drained and cultivated will often produce heavy crops. In Ireland, flax is sometimes successfully raised on peat-bog lands, with a clay substratum. But the best soil is a sound, dry, deep loam, resting on a somewhat porous and calcareous clay, otherwise termed marl. The good wheat soils of Canada are well adapted to the growth of flax. It should be borne in mind that stagnant water in the soil or subsoil is particularly injurious to the roots of this plant; and in such a case, thorough underdraining would be an essential condition of success.

*Preparation of the soil.*—Land intended for flax should be deeply ploughed in the fall, and well water-furrowed, that the surface be kept dry. This precaution will be necessary, even if the ground be naturally dry, or rendered so by underdraining, since in this country water will be sure to stagnate in low places in spring, whether the soil have covered drains or not. The ground should be again cross-ploughed in spring as soon as it is sufficiently dry; care being always taken not to get upon it when in a wet state. Instead of using the plough in spring,—provided the land had been deeply ploughed in the fall, the cultivator is considered by many to be preferable. This instrument, if sufficiently strong and heavy, will pulverize the soil 8 or 10 inches, and keep most of the dry, friable matter of the surface still at the top, which the plough will of course turn under, and bring to the top earth in a less favorable state for the seed bed. At all events, a deep tilth is always desirable, and the surface for several inches deep should be fine and mellow for flax seed to germinate and start advantageously. Such

a surface our long and intense winter frosts naturally produce in spring. Harrowing and rolling must be had recourse to as often as circumstances require to get a fine, deep tilth. The roots of flax being of a fibrous character, extend laterally and vertically to a considerable distance in search of food, frequently from 2 to 3 feet, where the soils suitably prepared.

Depth of tillage always adds to the feeding ground of a crop, and places increased supplies of mineral food at its disposal, and thus aids materially the development of its bulk. Although soils rich in organic matters are not generally so suited for flax as those of a medium class, still it is always desirable that the soil should be in good heart and condition, as the flax crop occupies the ground only a short time—fourteen to sixteen weeks, and must find its needed supply of food within a limited range, and in an available form. This condition of the soil is materially affected by the state of the division of its particles; a fine tilth, by exposing an extended surface to the action of the air, and of the rootlets of the plant, assists directly in the preparation of the food, and also in giving the plants better access to it. \* \* \* Keeping the ground *perfectly clear of weeds* is of essential importance to all crops, especially so to the flax crops, as the plant in its cultivated state is of a delicate and slender habit, but ill fitted to rough it in the fields, with the stouter and stronger indigenous plants, of a quick habit of growth, and of perhaps less powers of assimilation than those of our other ordinary crops; therefore, if we wish to carry on a successful cultivation, we must assist it by those means which experience and a proper knowledge of the requirements of the plant have shown to be usually followed by satisfactory results."

It is not deemed generally advisable to apply manure directly to the flax crop; strong manures especially, produce a coarse, and therefore less valuable fibre. Yet it should be remembered that a heavy and remunerating crop of flax cannot be grown upon poor ground. It succeeds best after a crop that has been liberally manured; particularly after

wheat or other cereals, which have been preceded by clean and deep cultivation. Flax has long had the reputation of being a very *exhausting* crop to the soil, and in many leases in the old country, it is absolutely excluded, or so fenced in by conditions, as to amount practically to exclusion. This, no doubt arose, in great measure, from the old practice of cropping land too frequently with flax, thereby lowering its standard of fertility in much the same way as thousands of acres of originally productive soils in Canada have been reduced by the too frequent repetition of wheat. But there can be nothing *peculiarly* exhausting in flax; all crops—especially the cereals, are exhausting,—particularly when both grain and straw are sold, and not returned in any form to the land. If flax is allowed to ripen, and both seed and fibre taken away, it becomes, no doubt, a “*scouring*” crop, particularly so if it has been heavy; but the same remark is more or less applicable to wheat, barley, turnips, potatoes, &c. If the seed of the flax be used in the feeding of cattle, though the whole of the straw may be sold off the farm, the increased richness of the manure will go far to restore to the soil those elements of fertility which the crop removed. It is not generally considered advisable by some to grow flax on the same land more frequently than once in ten years; not because it exhausts the soil more than other crops, but because good flax cannot be produced at short intervals. In Belgium, where this crop is cultivated extensively and with great skill and attention, it usually follows a grain crop, particularly oats. The following rotations are mentioned with approval by the committee of the *Royal Society for the promotion and improvement of the growth of flax in Ireland*—

“A rotation that would bring flax once in 10 years:—First year, potatoes; second, barley, laid down with grasses; third year, cut for soiling; fourth year, pasture; fifth year, flax, or the one half might be better in flax, the other in oats; so that, with the return of the rotation, which would be five years, the flax could be put on the ground which, in the last rotary course, was under grain, throwing a range of ten years between the flax crops

coming into the same ground. A gentleman of much practical knowledge, recommends the following as being the most profitable:—

1. Oats, after grass and clover; 2. flax, pulled in August: then ploughed and harrowed in with 2 cwt. of guano, and 2 cwt. of gypsum, (plaster), then sown with rape; 2. potatoes or turnips, well manured; 4. wheat sown in spring, with clover and rye grasses; 5. hay and clover; grazing; 7. oats; 8. flax, and winter vetches; guano as before mentioned; 9. parsnips, well manured; 10. barley, sown with rye-grass and clover; 11. clover and hay; 12. grazing; 13. oats. In Belgium where the climate is warm and dry, somewhat resembling that of Canada, the two following rotations, with slight occasional modifications, are considered good:—1. potatoes; 2. wheat; 3. rape; 4. oats; 5. Flax, with grass seeds; 6. grass seeds; 7. barley. On the better sorts of light lands, not well adapted for wheat, we find: 1. rye and turnips; 2. oats; 3. roots, (parsnips or carrots); 4. rye and turnips; 5. flax; 6. grass seeds. In Ireland the practice is somewhat similar. The following represents the prevailing rotations in the best flax growing districts:—1. roots, (potatoes or turnips); 2. wheat; 3. flax with grass seeds; 4. seed hay; 5. grasses grazed; 6. grasses grazed; 7. oats; 8. flax. Or: 1. oats; 2. flax; 3. roots; 4. wheat with grass seeds; 5. grass seeds cut; 6. grass seeds grazed.

*Special Manure for Flax.*—Recent chemical investigations have shown that the fibre of flax does abstract from the soil certain matters, although not in so large a proportion as several other commonly cultivated crops. To supply to the soil all the matters which the plant requires, with the exception of what is abstracted by the seed, which should be returned by saving the latter, and applying the manure of the cattle fed upon it, or an equivalent, if the seed be sold, so as to leave the land in the same state of fertility as before, the following compound has been proposed by Professor Hodges, of Belfast, (who has devoted much attention to these matters), as a manure which may be sown broadcast on the land, prior to the last harrowing before sow-

ing the flax seed—For a statute acre of land:—

|                                         | s. | d. |
|-----------------------------------------|----|----|
| Muriate of Potash, 30 lb—cost about     | 3  | 0  |
| Chloride of Sodium (common salt) 28lb   | 0  | 3  |
| Burned gypsum (plaster) powd'rd, 24 "   | 0  | 6  |
| Bone dust, 54lbs. ....                  | 3  | 6  |
| Sulphate of Magnesia (Epsom salts) 56 " | 4  | 0  |

11 3

*Selecting Seed, Sowing, &c.*—It is a matter of great moment in the successful cultivation of Flax that firm, plump, and uniformly ripened seed should be obtained, as much inconvenience and often considerable loss is sustained by negligence in this particular. Foreign seed, it is said, is universally preferred in Ireland, and the Belgians always select Baltic flax for their seed purposes. "For heavy soils the Dutch seed is frequently used, which is the produce of Riga seed once grown in Flanders. The American seed was at one time tried, as being somewhat cheaper; experience however, has shown that the plants had a tendency to grow branchy instead of a single erect stem, and although good for seed purposes, a large portion of the fibre was necessarily lost in scutching. Riga seed is everywhere considered the best for seed purposes. This, however, as is the case indeed with all foreign samples, is too dirty to admit of being used directly for the flax crop; as the amount of weeds mixed up with it would not only materially lessen and lower the value of the produce, but stock the land to the prejudice of after crops. The best plan to pursue is to obtain foreign seed sufficient merely to reproduce the quantity of seed required for the flax crop; and to sow this separately in wider drills, not less than 12 inches apart, so that it may be kept entirely free from weeds, and thus furnish a clean sample for the crop of the following year. This practice is generally followed in Belgium and in Ireland, where it is commonly known and sold as seed "one year from the barrel." The seed varies, of course, considerably in price; the Riga is, however, always the dearest: the Dutch and American being offered at a lower price, are consequently preferred by some growers."

*Sowing.*—The time for sowing flax will vary according to the season and the state of the land: the earlier it is done the better,

provided the necessary conditions are favorable. It can seldom be done in this country before May. Something depends upon whether the object be for fibre or seed; if the former, then the sowing should be done as early as possible; if the latter, or seed and fibre combined, the operation may be deferred a few days. In this country, vegetation is so rapid in its processes in the summer, and the crop grows so quickly, that the plants sown late have not time sufficient to mature and consolidate their tissues, which is so necessary for the production of good fibre, and which the slower vegetation of the spring months generally secures to those sown at an earlier period.

It is important to bear in mind, that land intended for flax should not be meddled with till the surface, at least, is thoroughly dry, and that a fine deep tilth is a necessary, and most advantageous condition;—and the surface should, by repeated harrowings, &c., be made as even as possible. The proportion of seed should vary; if fibre only be desired, the sowing should be thicker than when seed merely is required. In the former case, from 2 to 2½ bushels per acre may not be too much, while in the latter, or when both the fibre and seed are sought, the quantity may be reduced. It is better, as a general rule, to sow too thick than too thin; as in thick sowing, the stems grow tall and straight, with only one or two seed balls on each at the top, and the fibre will consequently be found much finer and superior to that produced from thin sown flax, which grows coarse and branches out, producing much seed, but a very inferior quality of fibre. For this reason, it is better to sow flax broadcast, than in drills; since the plants in the latter case, by having too much lateral exposure, are apt to grow coarse and bushy, and consequently producing flax of inferior quality. If drilling be adopted, a mode which certainly affords greater facilities for weeding, the rows should not be placed more than 8 or 10 inches apart, so as not to allow the plants much room for lateral growth. Whichever mode is adopted—(broadcasting at present is better suited to Canada) care should be taken to cover the seed at a uniform depth, otherwise it will not germinate and the crop ripen at

the same time. This uniformity of depth can generally be better effected by the drill, than sowing broadcast. Cover the seed with a light brush harrow, say from half to three-quarters of an inch deep, and if the weather be dry, give a finish to the surface by rolling.

"Both in Ireland and in Belgium, clover seeds are frequently sown down with the flax, and in the latter country, carrots are also met with, sown in the same manner. This practice, though very commonly seen, even in well managed farms, is only admissible when both the land and the seed are perfectly clean, and free from weeds. Even then, it cannot be recommended, as the two crops thus sown together have to struggle for the food which ought, under ordinary circumstances, to be devoted to one; and as the flax has to complete its growth long before the other arrives at maturity, it must suffer the most; while the operation of harvesting the flax cannot be effected without injury to the crop left behind it in the soil. The only attention the crop requires after it has been well got in, is to be kept clear of weeds. This, when it has been drilled, is done by hoeing carefully by hand or the expanding horse-hoe; when broadcasted, however, it must be either left untouched, or carried out in a different manner. In the British Isles, it is generally left to take its chance. In Belgium, where manual labor is far more largely and commonly employed than with us in farm work, and where the extravagance of our weed-growing farmers is rarely to be seen, the operation of hand weeding is never omitted, and is effected in a manner peculiar to the crop. As soon as the plants have acquired a certain growth, and the weeds begin to show themselves, suitable weather, of course being selected for the work, children are sent on to the field for the purpose of clearing it of all surface weeds. The work is done by them on their knees, which are well padded, to prevent them from crushing or injuring the young and tender plants; a small basket, or bag suspended from the neck, receives the weeds, which are collected from time to time by the overlooker and carried off the field. As this operation can only be done once, it is important that it be done effectually, and every weed is by

these means removed from the field. Care and consideration are required as to the best time for the work, as if left too late, the plant is liable to be injured by the pressure of the weeder; the precaution, too, is always taken of working against the wind, in order to give the young plant the advantage that might arise from the action of the wind in assisting it to resume its erect position as quickly as possible."

*Pulling.*—Flax is a plant of rapid growth, and in about ten weeks, if the soil and season are favourable, it will commence flowering, giving to the field a very pretty appearance. In case the ground has been properly prepared, and a sufficiency of soil uniformly deposited, both as regards distance and depth, the stems will grow erect with a few flowers chiefly at the top, all the plants attaining much the same height. The flowers are soon followed by the "capsules," or "bolls," as they are more familiarly called, containing the seed, which when fully ripe, should appear plump, shining and heavy. It is a matter of nicety and of much importance to determine the precise time when flax should be pulled. All agree that the fibre is in the highest condition for manufacturing purposes before the seed becomes quite ripe, or rather as soon as the lower part of the stem has assumed a decidedly yellow hue, which will generally be the case soon after inflorescence, or when the seeds are beginning to change from a green to a pale brown colour. In this case it is obvious that only a small quantity of seed can be obtained, and that not fully ripened, but such seed will be useful as food for cattle. Indeed linseed, whether steeped, crushed, or in the shape of cake, after much of the oil has been expressed by pressure, constitutes one of the most valuable and healthful cattle foods which the farmer can command. It promotes alike the growth of fat and muscle, and when given in moderation with drier food, such as hay, grain, &c., admirably serves to keep the bowels in healthy action.

When both fibre and seed are desired, which will be the case more or less with most Canadian growers for some time to come, great attention is required, as much will depend upon the exercise of a sound judgment not only as regards the quantity, but also the quality of the crop.

"The seed-vessels or capsules are of a globular form, with the top surface slightly drawn up to a point. On opening them, from six to ten, (more commonly the latter number) cellular divisions are seen, each occupied by a seed, which at first is a colourless integument, enveloping a watery mucilaginous matter. On examination in a day or two, it will be found to have assumed a more solid consistence, and the seed to have changed to a pale green colour. This the first point to be noticed, and not a day should now pass without observing the changes that take place, as these changes form the criteria by which the period of harvesting the crop should be regulated."

In Belgium, where flax culture has long been practised with distinguished success, the mode of proceeding may be briefly stated as follows:—A full-grown plant is selected, and the best matured and ripest capsule is taken. This is cut across with a sharp knife, and the section of the seeds examined. If they have become firm inside, and the outside has assumed a good deep green colour, the plant is considered fit for immediate pulling. At this time the entire plant will exhibit signs of its approaching maturity, —the bottom of the stalk will be seen to have assumed a yellowish tint, and have become much harder to the touch than it was before, good indications of an interruption to the circulation of the juices of the plant. If this altered condition be allowed to go on by the plant remaining in the ground, the change of colour will rapidly make its way up the stem until it reaches the capsules, and then the seeds will be found to be fully matured, quite hard, and to have assumed the dark colour with which we are so familiar in the market samples. The next stage of the plant, would be the bursting of the seed vessels and dissection of their contents, and the decay of the entire plant; but to preserve both seed and fibre, the plant should be harvested at the earlier stage, at which time the fibre is at its best condition. If left until the seeds are quite matured, the stems get hard and woody, and the fibre is apt to get much broken in the subsequent process of separation. Long experience has proved that this is the most profitable time to pull the flax; for although the seeds at that time are not fully ripe, yet if allowed to remain in the sheaf, they will absorb

from their integument a quantity of sap to render them sufficiently mature for the purpose of vegetation, though perhaps for commercial purposes their market value may not be so high as if allowed to stand a little longer in the field.

In order to get the greatest length of fibre, which is a matter of great importance, flax, unlike all other cereal crops, is pulled up by the roots; an operation performed by hand, and unless the operator is accustomed to the work, it becomes tedious and expensive. "The flax is pulled, each hand singly grasping a small handful carefully by the neck, just below the seed-vessels, and drawing it up out of the soil, and laying it in rows across the other. These are allowed to remain lying open on the ground for a certain time, generally one or two days; they are then collected together, and bound into small-sized sheaves or bundles, care being taken that the band shall be placed just under the seed-heads of the plant, and the bottoms or butts left unconfined and open. If the crop has been irregular in its growth, and the stems are of unequal lengths, it is desirable, as far as it can be managed, to pull them in different bundles, according to their length, as both in steeping and scutching much fibre is otherwise lost. It is also desirable, in binding them, that the butts should be gently pressed on the ground, in order to regulate the length of the different stems. After the sheaves, or "bundles," as they are termed, are bound, they are arranged in small stooks, usually of four, five, or six each, placed in a circle, the butts being well spread out, so as to admit the air freely to their centres,—the weather, and the condition of the crop when pulled, of course regulating the period they have to remain on the field."

We have heard of a machine worked by horse-power, for pulling flax, in the western States, but no information as to its efficiency has come to our knowledge. In the case of level land and the surface left rolled down after the sowing, a good careful mower, with a scythe suitably equipped, might cut the flax close to the ground, so as to leave but little fibre behind. The cost of hand pulling is considerable, even in Europe, varying from 15s. to 25s., sterling, per acre, and in this country the cost will be higher, particularly where people are unaccustomed to the work. A more expeditious and cheaper

method of pulling the crop than is generally practised is an important desideratum, which modern mechanical ingenuity, it is hoped, will ere long supply. When the flax in the field formed into shocks is sufficiently harvested, it can be taken into the barn or sheds, or made into a rick sufficiently protected against the weather, till it is required for steeping and scutching.

(Concluded in next number.)

### Elgin Flax Association.

St. Thomas, C. W., March 10, 1862.

*To the Secretary of the Board of Agriculture.*

Sir,—The growing importance of Flax culture has induced the farmers and the land owners in this neighborhood to form an Association for promoting the culture of it, and I beg to enclose a newspaper report of the first meeting.

You will observe that it is not intended to engage directly in the practical culture of Flax, but the Association will devote its energies in supplying seed, machines and instruction to those intending to engage in the cultivation, and in procuring the improved machines for scutching and furnishing models or patterns to persons who would become purchasers from the grower.

It is the object of the Association to call into existence a class of Flaxmen the same as the "linier" of France, who will purchase the stalk or straw from the grower, and will then prepare it in a proper state to be sold to the spinner.

This district has long been known for its peculiar aptitude as regards soil in producing flax of fine quality and in good yield per acre, and it is so far fortunate for the cause that an association of this nature shall have been here organized.

Experienced hands in flax farming were the early settlers in this county, but beyond growing small patches for domestic use; no extent of culture has been engaged in, but if the farmers can find a market for the stalk or straw, it is ascertained that they will willingly give it a permanent place in their rotation as a crop.

The Association in its present state of infancy requires every assistance to carry out its purposes and if it is in the power of your Board to lend its aid by any grant or contribution of money or seed, or any other valuable influence which your matured existence commands, it will render no inconsiderable service to an agricultural enterprise of great importance to this locality.

I have, &c.,

B. WALKER,  
Secretary.

Subjoined is the Report of the meeting above referred:

### FLAX CULTURE.

A large and influential meeting of the Farmers and Agriculturists of the County of Elgin, was

held at Hutchinson's Hotel, in this town, on Saturday the 1st instant, to take into consideration measures for forming an Association for promoting and encouraging the culture of Flax in this county.

Samuel Eccles, Esq., was unanimously called to the chair, and Mr. Walker was appointed Secretary.

Amongst the gentlemen present were George Claris, James Armstrong, Stephen Wade, Thomas Williams, Dr. Geo. Southwick, Hugh McIntyre, E. M. Yarwood, William Lipsey, John Marlatt, Richard Nicol, William Parker, James Mitchell, John Black, John Lanning, P. Bobier, John Rae, James Vansickle, Jacob Miller, John McCully, and many others.

The Chairman, in opening the proceedings, said: That the importance of Flax culture was attracting great attention throughout the Province, and he thought that it was very desirable to bring the matter more closely to the notice of the farmers and land owners, by organizing an Association such as the one at present contemplated. He saw present a great number of gentlemen who had been flax growers in the old country, and should be glad to hear their opinion on the subject. He had derived a great deal of information from the *Canadian Agriculturist*, and also from the letters of Mr. Donaldson. He then read some very interesting extracts, showing the value and importance of flax culture. He also called the attention of the meeting to an improved machine for scutching flax, invented by Messrs. Rowan, of Belfast; and concluded by calling on the gentlemen present to express their views on the object of the meeting.

Mr. Stephen Wade next addressed the meeting, and stated that there could be no greater proof of the importance that was felt in the flax culture than by the large and influential assembly of gentlemen then met. He then moved the first resolution, seconded by Mr. Rae, of South Yarmouth, which was unanimously adopted.

*Resolved*, that the persons now present be the first members of an Association for the purpose of encouraging and promoting the culture of flax, to be called the "Elgin Flax Association," and do hereby constitute themselves an Association accordingly. And that all persons who shall hereafter subscribe and contribute towards the objects of the Association, be members thereof.

Mr. Rae, a practical and experienced flax farmer, produced some very fine samples of his own growing and preparing, and in a lengthened address, urged the value and importance of flax culture. He showed the greater profit to the farmer, than in the present crops of wheat and other grain. He also stated his intention of extending its culture in his rotation of crops.

The second resolution was moved by James Armstrong, Esq., seconded by John Lanning, Esq.:

*Resolved*, That the intentions and objects of the Association are: to promote the culture of

flax in the County of Elgin, First, by publishing information and instruction to those willing to engage in the culture.

Second, by procuring and distributing Seed.

Third, by procuring improved machinery for scutching, and furnishing patterns and models to parties who would become purchasers from flax growers.

Fourth, by other means which may appear desirable to the managing Committee to be now appointed.

The third resolution was moved by Wm. Parker, Esq., seconded by John Marlatt, Esq.

*Resolved*, That the Managing Committee be composed of Samuel Eccles, E. M. Yarwood, George. Ciaris, Stephen Wade, George Southwick, Thomas Williams, William Lipsey, John Rae, Jas. Mitchell, Richard B. Nicol, and Charles Roe, with power to add to their numbers, and with full powers.

The fourth resolution was moved by Jacob Miller, Esq., seconded by John McCully, Esq.

*Resolved*, That the means for carrying out the objects of the Association, be furnished by voluntary contributions and subscriptions; and that George Claris, Esq., be the Treasurer of the Association.

A subscription was then opened, and contributions in aid of the Association made, and the Company then separated.

### The Agricultural Statute.

The following draft of an Act, to be submitted to Parliament for adoption, in amendment of the Consolidated Statute, 22 Vic. Cap. 32, has been prepared by the Committee appointed by the Agricultural Convention, held in the city of Toronto on 30th January last, in accordance with the resolutions passed at that meeting. It will be observed that this draft refers to the Agricultural Societies of Upper Canada only.

AN ACT TO REPEAL CHAPTER THIRTY-TWO OF THE CONSOLIDATED STATUTES OF CANADA, AND OTHERWISE TO PROVIDE FOR THE ENCOURAGEMENT OF AGRICULTURE, ARTS AND MANUFACTURES.

Her Majesty, by and with the advice and consent of the Legislative Council and Assembly of Canada, enacts as follows:

I. The Bureau of Agriculture and all Agricultural Societies, Associations, and Boards of Agriculture lawfully organized or established shall continue to exist, except in so far as the said Bureau, or such Societies, Associations or Boards are altered or affected by this Act.

#### BUREAU OF AGRICULTURE.

II. The Bureau of Agriculture shall continue to be attached to one of the Public Depart-

ments, and the head of that Department shall be charged with the direction of the said Bureau, and shall in respect thereof be known as the Minister of Agriculture.

III. The said Minister shall be *ex-officio* Member of all the Boards of Agriculture at any time established in this Province.

IV. The said Minister shall also receive all applications, drawings, descriptions, specifications and models for or relating to Patents for Inventions in this Province, and shall keep the records thereof.

V. The said Minister shall also be President of the Board of Registration and Statistics, and shall, under the general direction of the said Board, have charge of the Census and other Statistical Returns.

VI. It shall be part of the duty of the said Minister to institute inquiries and collect useful facts and statistics relating to the Agricultural, Mechanical and Manufacturing interests of the Province, and to adopt measures for disseminating or publishing the same in such manner and form as he finds best adapted to promote improvement within the Province, and to encourage immigration from other countries; and he shall submit to Parliament, within ten days after the opening of each Session thereof, a detailed and succinct Report of his proceedings.

VII. All Boards of Agriculture, Agricultural Associations, Agricultural Societies, Horticultural Societies, Municipal Councils, Boards of Arts and Manufactures, Mechanics' Institutes, Public Institutions, and Public Officers in this Province shall promptly answer official communications from the said Bureau of Agriculture, and shall make diligent efforts to supply correct information on all questions submitted to them respectively;—And any officer of any such Board, Society, Council, Institute, or other public Institution, refusing or wilfully neglecting to answer any question, or to furnish any information relating to the Agricultural, Mechanical or Manufacturing interests, or to the Statistics of this Province, whenever required so to do, either by the said Minister, or by any person duly authorised by him in that behalf, shall for every such offence incur a penalty of forty dollars, which shall be recoverable by any person suing for the same before any court of competent jurisdiction, and shall be paid to Her Majesty.

VIII. The Minister of Agriculture may, at any time, and from time to time, appoint any person or persons to inspect the books and accounts of any Society in the Province receiving Government aid, and being in any way in connection with the Bureau of Agriculture;—And all officers of every such Society, whenever required so to do, shall submit such books and accounts to such inspection, and truly to the best of their knowledge answer all questions put to them in relation thereto or to the funds of such Society.

IX. Out of the whole amount voted for the encouragement of Agriculture in Upper Canada, two and a half per cent thereof may be appropriated and devoted to the promotion of Agricultural instruction and information by the Board of Agriculture in that Section of the Province.

2. The Board of Agriculture may in its Reports to the Government indicate in what manner this sum should be employed;

3. Of the amount granted for the encouragement of Agriculture, ten per cent. in Upper Canada shall be placed at the disposal and in the hands of the Board of Agriculture for the purpose indicated by law.

#### BOARDS OF AGRICULTURE.

##### *Members and Officers.*

X. The Presidents and Vice-Presidents for the time being, of the Agricultural Associations hereinafter mentioned, and all Professors of Agriculture in Chartered Colleges, Universities, and other Public Educational Institutions, and the Chief Superintendents of Education in Upper and in Lower Canada, shall respectively be members *ex-officio* of the Board of Agriculture for that section of the Province in which they reside.

XI. Six members of each Board shall retire annually, and cease to be members thereof, unless re-elected, each seat being vacated every alternate year; but retiring members may continue to exercise all their functions until their successors have been duly elected, as hereinafter provided; and the names of the retiring members shall be published in the Agricultural Journals of the section of the Province in which they reside, or in such other public newspapers as the Minister of Agriculture may direct.

XII. The several County Societies in Upper Canada, shall, at their Annual Meeting, as hereinafter provided, each name two persons to act as delegates, who shall, at the meeting of the Provincial Association, at its Annual Exhibition, have each a voice in the election of members of the Board of Agriculture, and the election of such members shall take place on the evening of Thursday, in the first week of the exhibition.

XIII. The first election shall take place at the Annual Meeting of the Provincial Agricultural Association in one thousand eight hundred and sixty-two, and the six persons so elected shall replace the four members then next retiring from the said Board respectively; the next election shall take place at the Annual Meeting in one thousand eight hundred and sixty-three, to replace the remaining four members, whose term of service will then next expire.

XIV. Neither of the said Boards shall pay or allow any sum to a member thereof, for acting as such member, except the amount of his actual necessary expenses in attending the regular meetings of the Board; but each of the said Boards may appoint a Secretary and Treasurer

from among its members or otherwise, and may pay a reasonable salary for such services. The Treasurer shall give such sureties as the Board may require.

#### MEETINGS AND FUNCTIONS OF THE BOARD.

XV. The regular meetings of the said Boards shall be held pursuant to adjournment, or be called by the Secretary at the instance of the President or Vice-President, or upon the written request of any three members; and at least five days' notice of such meeting shall be given to each member:

2. The members of each of the Boards of Agriculture shall elect from among themselves a President and Vice-President at their first meeting after each annual election;

3. In the absence of the President and Vice-President, the Board may appoint a Chairman *pro tempore*;

4. Five members of the Board shall be a *quorum*.

XVI. It shall be the duty of the said Boards respectively:

1. To receive the Reports of Agricultural Societies, and before granting the certificates hereinafter mentioned, to see that they have complied with the law;

2. To take measures, with the approbation of the Minister of Agriculture, to procure and set in operation a model, illustrative or experimental farm or farms in their respective sections of the province, and in connexion with any public school, college or university, or otherwise, and to manage and conduct the same;

3. To collect and establish, at Toronto and Montreal respectively, an Agricultural Museum and an Agricultural and Horticultural Library;

4. To take measures to obtain from other countries animals of new and improved breeds, new varieties of grain, seeds, vegetables, or other agricultural productions, new or improved implements of husbandry or new machines which may appear adapted to facilitate agricultural operations, and to test the quality and usefulness of such animals, grain, seeds, vegetables or other productions, implements or machines;

5. The Boards of Agriculture may pass by-laws and adopt measures to allow persons desirous of practising as veterinary surgeons to undergo an examination; and upon proof to the satisfaction of the Board that they possess the requisite qualifications, may grant certificates of capacity to practise as veterinary surgeons to such persons.

XVII. The said Boards shall keep a record of their respective transactions, and shall, from time to time, publish, in such manner and form as to secure the widest circulation among the Agricultural Societies and farmers generally, all such Reports, Essays, Lectures, and other useful information as the said Boards respectively may procure and adjudge suitable for publication;

2. And if the said Boards, or either of them publish a monthly Journal, or adopt as their channel of communication with Agricultural Societies, the Agricultural Journals now published in Upper and Lower Canada respectively, then all Agricultural Societies receiving any share of the Public Grant shall give, at least, one month's notice of the time and place of holding their exhibitions in the Journals so published or adopted by the said Boards respectively.

XVIII. The said Boards shall transmit to the Bureau of Agriculture a copy of their resolutions, By-laws or other formal proceedings, immediately after the adoption thereof, and at the commencement of each year a detailed statement of receipts and disbursements, and a full statement of all property and securities held, made up to the thirty-first December of the previous year.

XIX. Each of the said Boards shall continue to be a body corporate, and may acquire and hold land and personal property for the purposes of its incorporation, and may sell, lease, or otherwise dispose of the same.

#### BOARDS OF ARTS AND MANUFACTURES.

##### *Members and Officers.*

XX. There shall be, in and for Upper Canada, a Corporation, composed as hereinafter provided, and called "The Board of Arts and Manufactures for Upper Canada."

XXI. There shall be, in and for Lower Canada, a Corporation, composed as hereinafter provided, and called "The Board of Arts and Manufactures for Lower Canada."

XXII. Each of the said Corporations may acquire or hold real or immovable property for the purposes of the Corporation, and may sell, exchange, lease, or otherwise dispose of or depart with the same from time to time; but no property shall be sold or otherwise alienated unless by authority of the Board, granted for that purpose, at a meeting held after special notice shall have been given of the business to be transacted, and by a vote of at least two-thirds of the members present at such meeting.

XXIII. The said Corporations shall respectively be composed of the Minister of Agriculture for the time being (who shall be *ex officio* a member of each); the Professors and Lecturers in the various branches of Physical Science in the Chartered Universities, and Colleges affiliated with Universities, in Upper and Lower Canada respectively; the Chief Superintendents of Education in Upper and Lower Canada respectively, for the time being, *ex officio*; the principal or staff officers of the Principal or Geological Survey in that section of the Province in which they may be respectively residents; the President for the time being of, and one delegate from each of the incorporated Boards of Trade; and the President of, and delegates from each Mechanics' Institute, or of any incorporated Arts Association, qualified as hereinafter mentioned, in Upper and Lower

Canada respectively—such delegates to be chosen annually as hereafter provided; and the Faculty of any institution of learning, of Collegiate rank, composed of at least five Professors or Lecturers—one of whom shall be a professor or lecturer upon Physical Science,—may, in the month of December in each year, elect one of such professors or lecturers to represent such College or Faculty upon such Board, and the President or Principal of such College or Faculty shall certify to the Board the name of the Professor or Lecturer so appointed.

XXIV. The incorporated Boards of Trade in each City and Town in Upper Canada respectively, shall at its last general meeting in each year, or at any special meeting held in the month of December, elect and accredit to the Board of Arts and Manufactures for Upper and Lower Canada, (according as its place of meeting is in Upper or Lower Canada) one of its body as a member thereof.

XXV. Each incorporated Mechanics' Institute in Upper or Lower Canada respectively shall, at its last general meeting in each year, or at any special meeting held in the month of December, elect and accredit to the Board of Arts and Manufactures in Upper or Lower Canada, one delegate for every twenty members on its roll, being actual working mechanics or manufacturers, and paying an annual subscription of at least one dollar each to its funds.

2. Each incorporated Arts Association in Upper or Lower Canada respectively, expending not less than one half of its annual income in the promotion of the Fine or Industrial Arts in Canada, shall, at its last meeting in each year, or at any special meeting held in the month of December, elect and accredit to the Board of Arts and Manufactures in Upper or Lower Canada, one delegate for every thirty members on its roll, who are paying an annual subscription of at least two dollars each to its funds.

3. But no Institution or Association shall be entitled to send more than fifteen delegates to either of the said Boards; and in case a vacancy occurs in the representation of any Mechanics' Institute, Board of Trade, or Arts Association, entitled to send delegates to either of the said Boards, such Institute, Board, or Association may, at its first meeting thereafter, elect a delegate or delegates to fill such vacancy.

XXVI. The names of the delegates elected, together with the names of the Presidents of such Mechanics' Institutes, Boards of Trade and Arts Associations, as aforesaid, shall be forthwith transmitted by the Secretary of the Institute, Board or Association electing them, to the Secretary of the Board to which they are elected, who shall thereupon inscribe their names upon the roll of the members of the said Board, for the year about to commence.

2. With the names of the delegates when transmitted by the Secretary of a Mechanics' Institute or Arts Association, there shall be

transmitted a statement, under the corporate seal of such Institute or Association, and verified by the written declaration of the Secretary transmitting the same, of the names of all the members on the roll of such Mechanics' Institute who are working mechanics or manufacturers, and are paying an annual subscription of at least one dollar each to the funds of such Institute; and the names of all the members on the roll of each Arts Association, who are paying an annual subscription of at least two dollars each to the funds of such Association.

3. If it appears by the said statement that any Mechanics' Institute or Arts Association has elected too many delegates, then the Secretary of the Board shall abstain from recording any of the names of the delegates of such Institute or Association, and shall submit the matter to the Board at its first meeting; and the said Board may, if they see fit, adjudge that such Mechanics' Institute or Arts Association shall not be entitled to any delegate for the year then next ensuing, or may decide by vote or ballot which delegate or delegates shall be rejected, and in this latter case the names of the remaining delegate or delegates shall be forthwith inscribed on the roll of members.

4. The wilful making of any false statement or declaration required or authorised by this Act shall be a misdemeanor, punishable by fine, in the discretion of the Court.

#### MEETINGS AND FUNCTIONS OF THE BOARD.

XXVII. The said Boards of Arts and Manufactures shall meet at the Cities of Toronto and Montreal respectively, twice in every year, that is to say, on the last Tuesday in the month of January and July, if such Tuesday be not a holiday, but if it be a holiday the meeting shall take place the next day thereafter, not being a holiday.

2. And the President of either of the said Boards, and, in his absence from the Province, or in case of a vacancy in the office of President, then the Vice-President, whenever he deems it necessary or is required by any ten members thereof so to do, shall call a special meeting of the same, in the interval between any two meetings.

3. But no such special meeting shall take place until seven clear days after a written or printed notice signed by the Secretary of the Board, and specifying the day, hour and place of meeting, and the object or objects for which the same is called, has been mailed to the address of each enrolled member of the Board.

XXVIII.—Each of the said Boards shall, at its regular meeting in January in each year, elect from among its members a President, Vice-President, and a Secretary and Treasurer, to hold office for the ensuing year, or until the election of their successors; and shall also elect a Council of not less than five nor more than nine

of their number for the management during the year, of such affairs of the Board as may by any by-law be entrusted to them.

2. The President and Vice-President shall be *ex officio* members of such Council, and the Secretary and Treasurer shall be *ex officio* a member of such Council, when elected or appointed from among the members of the Board, and not receiving any salary for such services; and a majority of the members of such council shall be a quorum for the transaction of business.

3. But the said Boards, or either of them, may at any time they shall see fit so to do by a by-law for that purpose, appoint some fit and proper person whether a member of such Board or not, to be the Secretary of said Board, at such salary and upon such terms as to the said Boards, or either of them may seem proper, and may remove such Secretary from time to time, and may appoint another in his stead and place; and the said Boards or either of them, may in their discretion require the said Secretary, so to be appointed as aforesaid, to discharge the duties of Treasurer for the said Board, in addition to the duties pertaining to the office of Secretary.

4. In case of a vacancy occurring in any of the said offices in the course of the year, either by death, resignation or otherwise, such vacancy shall be filled up by election as aforesaid at any regular meeting of the Board, or, in the interval, by the Council at any regular meeting thereof.

XXIX.—It shall be the duty of the said Boards of Arts and Manufactures:—

1. To take measures, with the approbation of the Minister of Agriculture, to collect and establish at Toronto and Montreal respectively, for the instruction of practical mechanics and artisans, Museums of Minerals, and Material substances, and Chemical compositions, susceptible of being used in Arts and Manufactures, with Model rooms, appropriately stocked and supplied with models of works of art, and of implements and machines other than implements of husbandry and machines adapted to facilitate agricultural operations; and also free Libraries of Reference containing Books, Plans and Drawings, selected with a view to the imparting of useful information in connection with Arts and Manufactures.

2. To take measures to obtain from other countries new or improved implements and machines; (not being implements of husbandry or machines specially adapted to facilitate agricultural operations) to test the quality, value and usefulness of such implements and machines.

3. And generally to adopt every means in their power to promote improvement in the Arts and Manufactures of the Province.

XXX.—The said Boards, with the consent and approbation of the Minister of Agriculture, may establish in connection with their respective Museums, Model Rooms and Libraries, and Schools of Design, on the most approved plane,

and furnished and supplied in the most complet, and appropriate manner that the funds at their disposal will admit of, regard being had to the claims thereon of the other objects for which they are hereby established.

2. And the Minister of Agriculture may cause duplicates or copies of models, plans, specimens, and drawings, and specifications, deposited in the Patent office, and upon which Patents of Invention have been issued, to be made from time to time, and placed in the Model Rooms, Museums or Libraries of the said Boards of Arts respectively.

3. The said Boards may also found Schools or Colleges for mechanics and artizans, and may employ competent persons to deliver Lectures on subjects connected with the Arts and Sciences, or with Manufactures, in such manner and place as the said Boards may from time to time direct.

XXXI.—The said Boards shall keep records of their respective transactions, and shall from time to time publish in such manner and form as to secure the widest circulation among the Mechanics' Institutes, and among mechanics, artizans, and manufacturers generally, all such Reports, Essays, Lectures and other literary compositions conveying useful information as the said Boards are respectively able to procure.

XXXII.—The said Boards respectively may make and ordain such By-laws, Rules, Orders and Regulations, not being contrary to this Act or to the laws of the Province, as they may deem necessary, touching the disposition and management of their funds, property and affairs; the holding and management of exhibitions of Works of Art and Manufactures, and the execution of the duties and the powers entrusted to them by this Act; and from time to time may repeal or alter the same and make others in their stead.

2. Copies of all By-laws, Rules, Orders and Regulations, and of the minutes of the proceedings of the said Boards, shall be transmitted forthwith after they are respectively made to the Bureau of Agriculture.

XXXIII.—All Mechanics' Institutes and Arts Associations receiving grants of money from the Government, shall be placed under the general supervision of the Boards of Arts and Manufactures for Upper and Lower Canada respectively, in like manner as the County Agricultural Societies are placed under the supervision of the Boards of Agriculture; and the said Boards shall receive from the Government, and pay over to the respective Mechanics' Institutes and Arts Associations any grants of money to which they may be entitled.

2. And it shall be lawful for each Board to retain for the use of its periodical Exhibitions, one tenth part of all such grants; and no Mechanics' Institute or Arts Association in Upper or Lower Canada shall be entitled to receive any grant of money from the Government, unless such Institute or Association has become incor-

porated under the general "Act respecting Library Associations and Mechanics' Institutes," chapter 72 of the Consolidated Statutes of Canada, or by special Act of Incorporation; nor unless such Institute or Association shall have transmitted to the Board of Arts and Manufactures for Upper or Lower Canada, a properly certified copy of its Annual Report for the past year.

3. And it shall be the duty of the respective Boards of Arts and Manufactures to send Agents to visit each incorporated Mechanic's Institute and Arts Association in Upper Canada respectively, whose duty it shall be to ascertain and report on the progress each Institute or Association is making in carrying out the objects for which the grants from the Government are made; and no Association or Institute shall be called a Mechanics' Institute within the meaning and provisions of this Act, unless it shall have at least twenty members enrolled as working mechanics or manufacturers, who are paying a subscription of at least one dollar each per annum to its funds.

#### AGRICULTURAL ASSOCIATIONS.

XXXIV.—The members of the Boards of Agriculture and of the Boards of Arts and Manufactures; the Presidents and Vice-Presidents of all lawfully organized County Agricultural Societies, and of all Horticultural Societies, Incorporated Mechanics' Institutes and Arts Associations, and all subscribers of one dollar annually, shall, in their respective sections of the Province, be, and constitute an Agricultural Association" for that section.

XXXV.—The Members of the Board of Agriculture and the Council of the Board of Arts Manufactures, and the Presidents and Vice Presidents of County Societies, Mechanics' Institutes, Arts Associations and Horticultural Societies, (or any two members whom a County Society, Mechanics' Institute, Arts Association or Horticultural Society may appoint instead of its President and Vice President) shall be the Directors of such Agricultural Association.

XXXVI.—The said Associations may each hold an annual or biennial Fair or Exhibition, which shall be open to competitors from any part of the Province.

3. The Directors shall hold a Meeting during the week of the Exhibition, and shall at such meeting elect a President and two Vice-Presidents, and shall also elect a Treasurer, who shall be paid a reasonable salary for his services; and shall appoint the place for holding the next meeting and Exhibition of the Association, and may appoint a local Committee of Management at the place where such Exhibition is appointed to be held.

4. And the said Boards of Directors respectively, may make such rules and regulations, not being contrary to the laws of the Province, as may be deemed necessary to prescribe the powers and duties of such local committees, and for the

proper management of such exhibitions; and for the disposition and management of their funds, property and affairs, and the execution of the duties and powers entrusted to them by this act; and the same from time to time to repeal or alter and make others in their stead.

5. But no repeal or alteration shall be made in any rule or regulation, unless one month's notice of such proposed repeal or alteration shall have been given in any Journals that may at the time be published by the respective Boards of Agriculture and Boards of Arts and Manufactures.

XXXVII.—The Board of Agriculture, and the President and Vice President of the Board of Arts and Manufactures, and one other member of the Council of said Board, to be elected annually by said Council, shall be the Council of the Association, with full power to act for and on behalf of the Association between the annual meetings thereof; and all grants of money, subscriptions, or other funds made or appropriated to, or for the use of the Association, (except money collected by or granted to any local committee for the local expenses of an Exhibition,) shall be received by and expended under the direction of the said Council.

2. And the President of the Board of Agriculture, and the President of the Board of Arts and Manufactures, shall be respectively *ex officio* President and Vice President of the Council of the Association, and the Secretary of the Board of Agriculture, together with the Secretary of the Board of Arts and Manufactures, shall be *ex-officio* joint Secretaries of the Association.

XXXVIII.—All contracts and all legal proceedings, by, with, or concerning the Association, shall be made and had with the Council of the Association in its corporate capacity, and no other contracts, agreements, actions or proceedings shall bind or affect the Association.

XXXIX.—The Council of the Association shall have power to grant licences to parties to sell refreshments upon the premises enclosed for the exhibition.

#### HORTICULTURAL SOCIETIES.

XL. Any number of persons, not less than twenty-five, may organise and form themselves into a Horticultural Society for any City, Town, Village, Township or Parish, or Union of two or more thereof together, either in Upper or Lower Canada, by signing a declaration in the form of Schedule A to this Act annexed, (but with the necessary alteration as to the name of the Society,) and subscribing a sum of not less than forty dollars annually to the funds thereof.

XLI. Such declaration shall be in duplicate, and one part thereof shall be written, and signed on the first page or pages of a book to be kept by the Society for recording the minutes of its proceedings during the first year of its existence, and the other part thereof shall be written and signed on a sheet of paper or parchment, and shall forthwith be sent by Post to the Minister of Agriculture, who shall, as soon as may

be after the receipt thereof, cause a notice of the formation of such Society to be inserted in the *Canada Gazette*.

XLII. Upon the insertion in the *Canada Gazette* of the notice of the formation of any such Society, it shall become a Corporation for the objects and purposes hereinafter mentioned, by the name applied to it in such notice, which shall be the same as that in the declaration transmitted by such Society, and may acquire and hold, lease and mortgage and alienate property, real and personal, for the purposes of such Society.

XLIII. Every Horticultural Society incorporated under this Act may make By-laws, not being contrary to the laws of this Province or to this Act, for prescribing the mode of admission of new Members and election of Officers, and otherwise regulating the administration of its affairs and property.

XLIV. Every such Society shall hold a meeting in the first week of the month of February, in each year, besides meetings at such other times as may be prescribed or provided for by its By-laws; and at such annual meeting a President, who shall also be a Director, a Secretary and Treasurer, and not fewer than three nor more than nine other Directors shall be elected.

XLV. The said Directors shall prepare and present to the annual meeting of the Society a report of their proceedings during the year, in the same manner as herein directed for County Agricultural Societies, and containing information under the same heads, save and except those which relate to Agriculture,—the object and purposes of Horticultural Societies being the same as those of Agricultural Societies, as hereinafter mentioned, but with reference to Horticulture only, and the said report shall be transmitted to the Secretary of the Board of Agriculture for that section of the Province in which the Society is situated, on or before the first day of April in each year.

XLVI. "Every Horticultural Society in any city, town, or incorporated village, incorporated under this act, or which may have been incorporated under any other act of the Provincial Legislature, shall be entitled to a public grant, equal to the amount subscribed by the members of such society and certified by their Treasurer to have been paid into his hands in the manner provided by the section of the act relating to Agricultural Societies, provided that the whole amount granted to any such society shall not exceed £100 in any year."

#### AGRICULTURAL SOCIETIES IN UPPER CANADA.

##### *County or Electoral Division Societies.*

XLVII. An Agricultural Society may be organized in each of the Electoral Divisions of Upper Canada for the purposes of Representation in the Legislative Assembly, in which there was not one embracing the limits of such Electoral Division already organized on the tenth day of June, one thousand eight hundred and fifty-seven,

Whenever fifty persons have become Members thereof by signing a declaration in the form of the Schedule A to this Act annexed, and paying each not less than one dollar annually to the Funds of the said Society; and a true copy of the said Declaration shall, within one month after the money has been so paid, be transmitted to the Board of Agriculture.

XLVIII. The object of the said Societies, and of the Township or branch Societies in connection therewith, shall be to encourage improvement in Agriculture or Horticulture, or both:—

1. By holding Meetings for discussion, and for hearing Lectures on subjects connected with the theory and practice of improved Husbandry;

2. By promoting the circulation of the Agricultural Periodicals published in the Province;

3. By importing or otherwise procuring Seeds, Plants and animals of new and valuable kinds;

4. By offering prizes for Essays on Questions of Scientific Enquiry relating to Agriculture or Horticulture, Manufactures and Works of Art;

5. And by awarding Premiums for excellence in the raising or introduction of Stock, the invention or improvement of Agricultural or Horticultural Implements and Machines, the production of grain and of all kinds of vegetables, plants, flowers and fruits, and generally for excellence in any Agricultural or Horticultural Production or Operation, Article of Manufacture or Work of Art;

6. The Funds of the Societies, derived from subscriptions of Members, or the Public Grant, shall not be expended for any object inconsistent with those above mentioned;

7. And the Directors of every such County Society, at any meeting, called by written notice as hereinafter mentioned, and in which notice the object of the meeting has been specified, may make, alter and repeal By-laws and Rules for the regulation of such Society and the carrying out of its objects.

XLIX. The first Meeting for the formation of a County Agricultural Society in Upper Canada under this Act, shall be called by the Warden of the County or Union of Counties in the third week of January in each year, at which Meeting the Election of the various Officers shall take place, and the Society so organized shall be deemed the County or Electoral Division Society and shall be entitled to receive the Provincial Grant hereinafter provided; and all subsequent Annual Meetings after the first Meeting shall be called and held as provided in the next following section of this Act.

L. The said Societies shall hold their Annual Meetings in the third week of the month of January in each year, and shall at such meeting elect a President, two Vice Presidents, a Secretary and Treasurer, and not more than seven Directors.

LI. The Presidents of the several Township Agricultural Societies, within the County or Electoral Division, shall, in addition to those before named, be *ex officio* Directors of the County Society, provided that each such Township society shall have upon its list of members at least ten persons who are also members of the County Society, and paying not less than one dollar each, or that such Society shall otherwise have contributed ten dollars annually to the funds of the County Society; and the said officers and Directors shall, for the year next following the annual meeting, and until the election of their successors, exercise all the powers invested in the County Society by this Act.

LII. The Meetings of the Officers and Directors shall be held pursuant to adjournment, or called by written notice given by authority of the President, or in his absence, the Senior Vice-President, at least one week before the day appointed; and at any meeting five shall be a quorum.

LIII. The said Officers and Directors shall, in addition to the ordinary duties of management, cause to be prepared, and shall present at the Annual Meeting, a Report of their proceedings during the year, in which shall be stated the names of all the Members of the Society, the amount paid by each being set opposite his name, the names of all persons to whom premiums were awarded, the amount of such premiums respectively, and the name of the animal, article or thing, in respect of which the same was granted, together with such remarks and suggestions upon the Agriculture and Horticulture of the County, and Arts and Manufactures therein, as the Directors are enabled to offer;

2. There shall also be presented to the said Annual Meeting, a detailed statement of the receipts and disbursements of the Society during the year;

3. The said Report and statement, if approved by the meeting, shall be entered in the Society's Journal, to be kept for such purposes, and signed by the President, or a Vice-President, as being a correct entry, and a true copy thereof, certified by the President or Secretary, for the time being, shall be sent to the Board of Agriculture, on or before the first day of April next following.

LIV. The County Society shall receive the Reports of the Township or Branch Societies, and shall transmit them to the Board of Agriculture, with such remarks thereon, as will enable the said Board to obtain a correct knowledge of the progress of agricultural improvement in the County or Electoral Division.

LV. The said Officers and Directors shall answer such queries and give such information, as the Board of Agriculture, or Minister of Agriculture, may, from time to time, by Circular Letter, or otherwise, require, touching the interests or condition of Agriculture in their

County or Electoral Division, and generally shall act as far as practicable upon the recommendations of the Board.

### *Township Societies.*

LVI. A Township or Branch Agricultural Society may be organized in each Township in Upper Canada, in which there was not one already organized on the tenth day of June, one thousand eight hundred and fifty-seven, or in any two or more such Townships together, whenever a sufficient number of persons, not less than twenty-five, become Members, by signing a declaration in the form of Schedule A, to this Act annexed, and subscribing a sum not less than forty dollars annually, to the funds thereof; and a true copy of the said Declaration, certified by the President or Vice-President of such Society, shall be forthwith transmitted to the County Society.

LVII. The said Societies shall hold their Annual Meeting on the second Thursday of the month of January in each year, and shall elect a President, Vice-President, Secretary and Treasurer, and not fewer than three, nor more than nine Directors.

2. In the event of the Secretary or Treasurer dying or resigning office during the term for which he has been elected, it shall be the duty of the Directors and they are hereby empowered to nominate and appoint a fit and proper person to fill the office for the unexpired term of the person so dying or resigning as aforesaid.

LVIII. The said Officers and Directors shall prepare and present to the Annual Meeting of the Society, a Report of their proceedings during the year, in the same manner as hereinbefore directed for County Societies, and containing information under the same heads, and shall transmit a true copy thereof, certified by the President or Vice-President, to the Secretary of the County Society, in time for the Annual Meeting thereof in the month of January.

### GENERAL PROVISIONS RELATIVE TO AGRICULTURAL SOCIETIES IN UPPER CANADA.

LIX. The Exhibition of the County Society shall be held wherever the majority of the Directors, or of a quorum thereof think fit, giving due and public notice thereof:

2. And two or more County and Township Societies may, by agreement between the Directors thereof, or a majority of Directors of each such Society, unite their Funds, or any portion thereof, for the erection of suitable buildings in which to exhibit Articles of Produce or Manufacture or Work of Art, or for Annual or Extra Shows, or for Ploughing Matches, or for any other purpose likely to promote the welfare of any one or more Counties or Townships, in Agriculture, Horticulture, Arts or Manufactures, and may acquire, by purchase or lease, and hold sufficient land for this purpose, from time to time, and may exchange or sell the same.

LX. Whenever the President and Secretary of the Board of Agriculture, certify to the Minister of Agriculture, that any County Society has sent to the said Board, Reports and Statements, as required by this Act, for the year then last previous, and also certify that the Treasurer or other officer of the said Society has, on or before the first day of July, of the current year, transmitted to the said Board, an Affidavit, (which may be in the form of the Schedule B, to this Act annexed, and may be sworn to before any Justice of the Peace,) stating the amount subscribed for that year, and paid to the Treasurer of the County Society by the members thereof, and by the several Township Societies of said County, the Governor may issue his Warrant in favour of such County Society, for a sum to be paid out of any unappropriated moneys in the hands of the Receiver General, equal to three times the amount appearing by the said affidavit to be in the hands of the Treasurer:

2. But no grant shall be made unless one hundred dollars be first subscribed and paid to the Treasurer:

3. And the whole amount granted to any such Electoral Division Society shall not exceed eight hundred dollars in any year;

4. Except that each of the Counties of Lennox and Addington, Huron and Bruce, separately, shall be entitled to receive a sum not to exceed eight hundred dollars, on the conditions specified in this Act, and that the Counties of Prince Edward, Welland, Haldimand, Grey, Halton, Kent, Carleton, Essex, Lambton, Lincoln, Norfolk, Peel and Perth, shall each be entitled to receive as heretofore a sum not exceeding one thousand dollars in any year, and on the conditions aforesaid.

LXI. The City of Toronto,—the City of Kingston,—the City of Hamilton,—the Town of Breckville,—the Town of Niagara,—the Town of Cornwall,—the City of London,—and the City of Ottawa, as bounded for purposes of Representation in the Legislative Assembly,—shall each be entitled to receive a sum not exceeding four hundred dollars for the encouragement of Horticulture, Agriculture, Manufactures, and Works of Art within their respective limits:

2. Provided, that a sum equal to one third of the amount to be so paid by the Government, is subscribed and paid to the Treasurer of a Society to be formed within such Electoral Division, in the same manner as County Agricultural Societies under section forty-seven of this Act, and to be called "The Society for the Upper Canada Electoral Division of \_\_\_\_\_," or as the case may be.

LXII. Every Township or Branch Society organized according to the Act sixteenth Victoria, chapter eleven, or to this Act, and sending a report of its proceedings to the County Society, as hereinbefore required, shall be entitled to a share of the grant to the County Society, in pro-

portion to the amount subscribed by the members of such Township or Branch Society, and deposited with the Treasurer of the County Society, on or before the first day of May in each year, as compared with the amounts so deposited by the other Township and Branch Societies of the County; and the sum so deposited by any Township or Branch Society shall be repaid, along with its share of the Public Grant, so soon as the said grant is received by the County Society:

2. Provided that three-fifths and no more of the sum so received by any County Society shall be subject to division among Township or Branch Societies; and provided that the declaration mentioned in section fifty-six shall be deemed a sufficient report for the first year in which any Township or Branch Society has been organized, and that no Township or Branch Society shall thus receive more than three times the amount so deposited by it as aforesaid;

3. And provided that nothing in this Act contained shall be construed as admitting any member of a Township Society, in virtue of his subscription thereto, and without further subscription to the County Society, to any of the privileges of a member of such County Society.

LXIII. The Board of Agriculture shall receive from Government, and pay over to the County Societies, the Public Grants, to which they are respectively entitled, and the said Board may retain for the use of the Agricultural Association, one tenth part of all such grants.

LXIV. Any Treasurer or other officer of any County, Township or Branch Society, who makes affidavit that a subscription, or any sum of money, has been paid to him for the Society, when it has not been so paid, or who returns any such subscription, shall forfeit and pay to Her Majesty the sum of forty dollars for every such offence, and shall be guilty of perjury and be held liable to all the penalties with which the law visits that crime.

LXV. The several County Societies organized according to the provisions of this Act, or of the said Act sixteenth Victoria, chapter eleven, or of any Act thereby repealed, shall be and continue Bodies Corporate, with power to acquire and hold land as a site for Fairs and Exhibitions, or for a School Farm, and to sell lease, or otherwise dispose of the same; And, any Township or Branch Society, lawfully organized as aforesaid, may, at any Regular Meeting, adopt a Resolution that the said Society is desirous of being incorporated, and upon filing the said resolution with the Secretary of the Board of Agriculture, such Society shall thenceforth be and become a Body Corporate, and shall have like powers with County Societies.

LXVI. Any County or Township Society, or the Municipal Council of any County or Township of Upper Canada, may purchase and hold land for the purpose of Establishing a School-

Farm to instruct pupils in the Science and practice of Agriculture; And any Society and any Municipal Council may purchase and hold such School-Farm conjointly or otherwise, and make all necessary rules and regulations for the management thereof; provided that not more than one hundred acres of land shall be so held by any Society or Council, whether conjointly or otherwise.

LXVII. Whenever any property, real or personal, in any one or more of the Electoral Divisions, originally belonged to the County Society of the County of which the said Electoral Division formed a part, the said property or the value thereof shall be equitably apportioned or divided by Arbitrators or a majority of them, one to be appointed by the Directors of the Society in each such Electoral Division, and another Arbitrator to be chosen by the Arbitrators so appointed.

LXVIII. The word "County" in the sections of this Act applying to Agricultural Societies in Upper Canada, means "Electoral Division," except where such construction is inconsistent with the express enactment in which such word is used; And the words "Electoral Division," whenever used herein, mean a Division for purposes of representation in the Legislative Assembly:

2. And the provisions of the said sections with regard to grants and Electoral Divisions, conditions of grant, &c., &c., shall extend to any new Counties or new Electoral Divisions to be formed in Upper Canada; except that no new Electoral Division shall be entitled to more than eight hundred dollars.

#### MUNICIPAL AID TO AGRICULTURAL SOCIETIES IN UPPER AND LOWER CANADA.

LXIX.—The Municipality of any City, Town, Village, County or Township in this Province, may grant money or land in aid of the Agricultural Association for that section of the Province to which the Municipality belongs, or of any Agricultural or Horticultural Society whatever duly organized under this Act, within the limits of such Municipality.

#### SCHEDULE A.

We whose names are subscribed hereto, agree to form ourselves into a Society, under the provisions of the *Act for the encouragement of Agriculture, Arts and Manufactures*, to be called the (County, Electoral Division, Township or Branch *as the case may be*,) Agricultural Society of the County (or Electoral Division) of (or Township of ) ; and we hereby severally agree to pay to the Treasurer yearly, while we continue Members of the Society, (any Member being at liberty to retire therefrom, upon giving notice to the Secretary, at any time before the annual meeting, of his

Justice of the Peace for the  
County of

The following interesting paper from a recent number of the *Mark Lane Express*, will afford many useful suggestions to our readers. The circular of the Wool Supply Association, with specimens of different kinds, was received by our Board of Agriculture, and some notices thereof will be found in our last volume. We are of opinion that with perseverance and sound judgment a great deal more in the production of the longer sorts of wool may be done in Canada than is generally imagined.—ED.]

increased demand for long wool by the worsted trade, which has led the manufacturers and Bradford Chamber of Commerce to enter into direct communication with the several wool-producing countries, in order to stimulate greater exertion in the production of that class of wool. Our observations were then directed specially to the Cape wools and to the temper in which the suggestions had been received by the Cape flockmasters. But the whole subject has a far wider range of application than one colonial district, since our foreign supplies of wool are drawn from a great number of quarters, and every description of climate. As our journal is most likely to pass into hands abroad that have not been reached through the official channels by which the circular of the Chamber of Commerce for the worsted district was issued, we shall draw attention prominently to their requirements, and pass under review the different producing districts and the peculiarities of the wool they supply.

The increase in the imports of foreign and colonial wool in the last five years has been very large. In 1856 we received 124½ million pounds; in 1860, 145½ million pounds; and in the eleven months of the past year 127¼ million pounds. There is a new item in the Board of Trade returns this year, nearly 15 million pounds of "woolen rags, torn up to be used as wool."

The increased supplies of wool have been, however, almost exclusively of a nature to adapt them to the woollen rather than to the worsted manufacture. Those interested in this latter branch of industry are anxious to stimulate the growth of wool suitable for their wants. The qualities they require give to the wool a higher marketable value for all purposes of manufacture, and are therefore well deserving the attention of growers, collectors, and shippers of wool.

The wool (the increase of which they desire to promote) should have a staple from four to seven inches long, according to its fineness, and should, as far as possible, be uniform in quality throughout its whole length; bright and lustrous in its appearance, or soft and kind to the touch, of good spinning properties, free from burrs or other vegetable fibre. It should also be well washed before it is clipped; or where this is not practicable, care should be taken that it be not cotted or felted in drying. It is most desirable to retain the whole natural length of the staple, by only clipping the lambs or sheep once during the season's growth, unless local causes render it absolutely necessary to do so oftener. It is also very important that a proper classification of wool should be made in packing, and that the packing should be thoroughly trustworthy and fair.

An improvement is already manifested in the wool of some countries, and it is thought this might be made general, if proper care were taken in the selection of breeding sheep, particularly of the rams, and, where necessary, by the introduction of new blood. The flocks

should, as much as possible, be pastured upon succulent grasses, similar to those grown in Great Britain. The destructive effects of drought or cold, or other climatic causes which check the growth of the grasses, by depriving the sheep of their necessary supply of food, and rendering the staple tender, ought to be prevented by a constant supply of food throughout the whole year.

The Wool Supply Association, in their circular, pass over in succession the different countries where wools suitable to the worsted trade are cultivated, and point out the faults belonging to each description. We shall quote some few of these practical observations, supplementing at the same time such statistics as will serve to show the quantity we import from these quarters. The wool imported from Portugal, which now amounts to about  $4\frac{1}{2}$  million pounds, is long-stapled and bright, but with a sprinkling of grey and reddish hairs, which depreciate the value and limit the competition. The sheep, also, for want of attention, are apt to produce cotted and yellow-tinged fleeces, which only realize here about two-thirds of the value of free open-stapled white wools. The receipts from Oporto have increased considerably of late years; but a good portion of the increase consists of wool from a lower breed, and is called here "Mountain Oporto." This description is part long, very coarse stapled, and the other part of the fleece is short and dull-looking wool, unsuitable for the same purposes as real Oporto, and realizing twenty-five per cent. less price. By attention this mountain wool might be raised to an equal character with the usually good description received from Oporto.

In Iceland the effect of a cold climate acting upon sheep left to nature, has been to produce a wool consisting of a long spiry coarse top, with a fine downy bottom, which for English consumers is very objectionable, and reduces the value. The annual production in the island is probably about 8,000 to 10,000 packs, and we import of Danish and Iceland wool about  $2\frac{1}{4}$  million pounds.

If the Russian sheep farmers continue as they have hitherto done, to increase the numbers of their flocks rather than to improve their breeds, it may safely be predicted that their export of wool will decline from year to year. It is a notorious fact that the washing and assorting of wool in Russia—operations of great importance—with a few laudable exceptions, are performed with such consummate slovenliness as to be elsewhere unparalleled. Indeed, such is the absurdity and desire for gain of some flockmasters, that they speculate on the increment of weight from dirt, and wash their sheep in muddy water, in the expectation that the fleece will thus bring in more money; the fact being that the price offered by the merchant, who is quite alive to the trick, is in consequence so small, that the advantage redounds to him, and not to the farmer. Again, in assorting the wool, no

separation is made of the different parts of the fleece. Sometimes, too, the wool of dead animals is thrown in among that shorn from living ones; and for ordinary wools, the product of different breeds is indiscriminately mixed. This negligence is detrimental, not only to the sale of wool abroad, but also to the fabric of their home-manufactured cloths, especially in regard to their receiving the dye. In packing and transporting the wool, the negligence exhibited is as great as in any other department, and forms a striking contrast with the care bestowed upon those processes in other countries. The wool is often found to contain a mixture of heterogeneous trash, such as waste of hay and straw, fragments of bags, grain husks, &c. It is also baled in coarse bags of bad quality, which are easily torn, and as the bales are exposed to the weather during the transport, nothing is easier than for moisture to penetrate them.

Deterioration of breeds has been manifested in Russia for some time past, not only in the merinos, but also among the indigenous sheep. There are in that country several sorts of these common breeds, some of which yield such coarse wool that it can only be used for the manufacture of the most inferior felts, or in the caulking of ships. But there are also others, of which the wool is employed for several sorts of ordinary cloths, and might be improved, at least up to a certain point, by judicious crossing and more careful management. Instead of being regenerated by coupling with rams of a better breed, they are allowed to mix with races more inferior still; and their scanty nurture in winter, in connexion with the inclemency of the season, likewise has a tendency to render their wool coarser. Out of about 50,000,000 of sheep in Russia, there are not more than one-fifth fine-woolled sheep. The Donskoi sheep is probably in a state of nature, or at least partially so, and the Crimean entirely so. Both these admit of great improvement, and by care for a few years a long-stapled good combing wool of fine quality might be produced, upwards of 30 per cent more valuable. At present we receive about  $8\frac{3}{4}$  million pounds of wool from Russia.

The wools from Turkey (Asiatic and European provinces), which now reach us to the extent of 1,000,000 lbs., are usually very scurfy and kempy, both of which serious faults may be eradicated by attention. It seems as if most of the wools got no care at all. There is the basis of capital combing wool, even if the growers cross with their own selected rams, without the introduction of English sheep.

The Egyptian wool, of which we import about 2,000,000 lbs., possesses many of the properties sought for by the consumers here. The staple might be long enough if the native collectors and growers did not induce the practice of shearing twice in the year. The wool is bright, sound and silky, but is sometimes spoiled by a sprinkling of grey hair; also by the admixture of ill

bred, rough, fuzzy wool, known in trade as Syrian.

The wool received through Mogadore—under 1,000,000 lbs.—is deficient in lustre, kempy, and of a brownish colour; but, by judicious crossing with English blood, it could be brought to resemble our breeds, and find a large and remunerative market.

In the East Indian and Persian wools, of which considerable supplies are now coming forward (upwards of 20,000,000 lbs. per annum) improvement has already commenced, and a large field awaits further development. Each year's imports are collected from a wider range, and as we penetrate into a more temperate region we find wool of a longer and sounder staple, assimilating more closely to our English descriptions than the short hair wool that is usually grown near the tropics. East Indian wool has a tendency to be burry and scurfy, with a slight mixture of gray hairs. The staple is generally too short.

Our supply of wool from China has been on the decline, as it found little favor here. The imports have dropped from 300,000 lbs. to about one-fifth of that quantity. It is unusually soft, short-stapled wool, looking neither like fleece nor lamb, and is very cotted, kempy, and yellow. No attention seems to be bestowed upon it by the growers, but when a regular demand arises, the Chinese will, no doubt, give more attention to it, and effect desirable changes. From the extraordinary fecundity of the sheep, large quantities might be produced.

It is gratifying to see that the Central Farmers' Club has the growth of lustre wool on the card for this year; while the correspondent of a local paper thus refers to the home growth; "The lustre wool is not much in request, and I should be especially glad of a well-reasoned and authoritative opinion as to whether or no its regular production could be depended on upon the light farms of Hants and Wilts? My own opinion is that a flock of Lincolns would, if the rams were always brought from Lincolnshire, and the flock regularly fed on turnips, &c., retain the lustrous character of their fleece."

### Changes of the Atmosphere.

*(From the Mark Lane Express.)*

The mutual dependence of the various phenomena exhibited within the limits of that vast aerial ocean, the atmosphere, and the modifications that each meteorological process undergoes through the agency of all the rest, has tended to retard, and render extremely difficult, its practical application to the wants of every day life. The complexity of the causes which disturb our atmosphere is so intricate, that it becomes a nice and delicate task to determine what is cause and what effect, so completely does the one seem to take the place of the other, according to the point of view from which we make

our observation. For this cause meteorology seemed rather to belong to the region of speculative philosophy than to rank as one of the exact sciences; and the only persons by whom it was much followed seem to have placed their faith in the very problematic power of empirical predictions, rather than attempt to trace causes from observed effects. As an example of the many and different modifying processes through which nature works, let us spend a few minutes in considering the causes which operate on some of the currents of air, so regular within certain limits, yet so varied in our own latitude. Sufficient attention has not been paid to the subject of the winds, either by the agriculturist or the philosopher; a fact in a great measure owing probably to the want, till late years, of self-recording anemometers. A good trustworthy wind vane is a very useful thing in any case, and should be often consulted; but we can hardly hope for any very concise results, unless we have the means of tracing, through a long period of time, every movement and change in the direction. It is only from an uninterrupted series of such records that we can expect to establish, finally, the periods of so apparently erratic an element as the wind. One can scarcely realize the fact that the gentle air as it fans the bronzed cheek of southern Europe, and with a soft persuasion wafts the tiny skiff over the unruffled waters of some placid lake, is the same element that, when acted upon by certain forces, unseen, yet not the less powerful, hurls destruction over land and sea, turning the calm waters, where the ship like "a painted thing upon a painted sea" rides at anchor, into a raging and furious flood—a remorseless and quick destruction alike for ship and human life. The fiery simoon and sirocco of the Indies, the pestilence-bearing winds of western Africa, the tempestuous gales that crush and tear to atoms the floating homes of hundreds, filling the coasts of more northern climes with death and horror, are all of one family with the soft breeze that wakes with gentle murmur a summer morning, or the cooler airs that, as the shades of night draw on, seem to sigh for the departing day. Truly we cannot tell "whence it cometh or whither it goeth," and can only trace its course over a limited space by the marks of its iron foot-step, or by the more refined appliances of science. But who can tell the place of its birth? The human mind can hardly conceive by what Titanic forces the light and buoyant air is acted upon, that in its headlong course it overturns the strongest monuments of human art, as well as the giant inhabitants of forests, whose seeds, perchance, had germinated under the same sun that cheered our Saxon forefathers.

We shall better understand the various disturbing causes which exert their influence on the atmospheric pressure, if we commence by examining what would be its state if but few of the causes existed. Let us suppose our earth

covered with water of an equal depth, then there would exist but little variety either in the force or direction of atmospheric waves. The only causes which would under these circumstances, operate to give the air motion would be the rotary motion of the earth round its axis and its position in regard to the sun. In addition, suppose the sun to be always in the equinoctial; in that case, we should have a system of winds like those existing at certain times of the year at the tropics called the "trades" which would be invariable, the mean line of direction prevailing at the equator, whilst the earth's motion would modify the currents as we went towards either pole gradually. But this constancy is wisely upset by two main causes, viz., the movement of the sun in declination, which tends to carry the middle line below or above the equator, according to the season, by  $23\frac{1}{2}$  degrees; the other disturbing cause is to be found in the existence and peculiar form of the continents. There are many other causes of wind of a local character: the variation in colour of the landscape, and, consequently, the unequal radiating power of different tracts of land, will tend to disturb the atmospheric equilibrium; whilst the difference between the radiating and absorbing power of the sea and neighbouring land causes those diurnal currents experienced by the sea, especially in tropical regions, known as land and sea breezes. During the day the land acquires a temperature higher than that of the adjacent ocean; the atmosphere above it consequently becomes rarified, and the air from the sea flows towards the land, to occupy the partial vacuum produced there. In proportion as the heat of the land goes on increasing, the force of the sea breeze increases also; and this continues up to about 2 or 3 p. m., varying slightly with the season. After that time, the land more readily giving off the heat which it received during the morning hours, the land cools much more quickly than the sea, and the sea breezes cease about sunset. During the night the land continues to cool, and the air over the sea comparatively warmer; and the air therefore sets from the land, where it is denser towards the sea.

Now, when we consider how many causes there are combining to make the sun's action very unequal over the surface of the globe, and the consequence in the temperature of the air lying over it, we can hardly fail to see the reason why the currents of air coming to us are so diversified both as regards strength and direction; our removal from the limits of the "trades" being another reason of our not experiencing the periodicity of the tropics. Hitherto, as we have remarked, the observations relative to the phenomena of the wind have been very inadequate for the purpose of determining much about the laws by which they act in our latitude, owing to the number of disturbing causes. What is a *cause* in the tropics becomes

an *effect* in our latitude; the cause existing beyond our limits. For example, the temperature is the cause, perhaps of a certain wind in the tropics. Now with us, it frequently happens that the *wind* is the cause of a change in our temperature. The element of meteorology will, no doubt, as observations become more numerous, be much better understood than it is at present; and as the wind affects the climate of our globe to so large an extent, by bearing moisture and heated air to regions remote from the places of their birth, and also by causing the circulation of differently heated oceanic currents, a better knowledge of its force, direction, &c., both as regards the more extended movements, as well as the influence of local peculiarities, is much to be desired.

### The Parsnip.

The parsnip is one of the most valuable roots that can be grown. In the Island of Jersey it is used almost exclusively for fattening both cattle and swine. According to La Couteur the weight of a good crop varies from thirteen to twenty-seven tons per acre. When parsnips are given to milch cows, with a little hay, in the winter season, the butter is found to be of as fine a colour and excellent flavor as when the animals are feeding in the best pastures. As parsnips contain six per cent. more mucilage than carrots, the difference may be sufficient to account for the superior fattening as well as butter-making quality of the parsnip. In the fattening of cattle the parsnip is found superior to the carrot, performing the business with more expedition and affording meat of exquisite and highly juicy flavor; the animals eat it with much greediness. The result of experiment has shown that not only in neat cattle, but in the fattening of hogs and poultry, the animals become fat much sooner, and are more healthy than when fed with any other root or vegetable, and that, beside, the meat is more sweet and delicious. The parsnip leaves being more bulky than those of carrots, may be mown off before taking the roots, and given to oxen, cows or horses by which they will be greedily eaten. Another thing in favor of parsnips for this country is, that the frost does not injure them. They may remain in the ground until spring, when they make a splendid feed, at a time when every other kind of root or green thing is scarce, or they may be slightly buried, where they can be obtained almost any time during the winter. On account of their rapid growth when young, the weeding is less trouble, than weeding carrots.

**CUTTING SEED POTATOES.**—The effects of dividing potatoes as seed have often been discussed, some stating it as their belief that the plan was good, others as vehemently insisting that

it was as wrong in principle as it was bad in practice. Certainly, reasoning from analogy, the latter seems to have the best of the argument. May not the dividing of the seed year after year be stimulative of disease—at least by weakening the powers of germination of the plant predispose it to disease? The following is the result of an experiment on the growing of potatoes. The experimenter planted 27 holes with whole potatoes; 23 with cut potatoes, three pieces in each hole; 23 holes with cut potatoes, two pieces in the hole. The seed used was averaged by weight and size. The holes of uncut potatoes yielded  $55\frac{1}{2}$  lbs., the 23 with three sets in each  $27\frac{1}{2}$  lbs., and the 23 holes with two sets  $39\frac{1}{2}$  lbs. The treatment as regards manure, soil, &c., was alike for all the plots.

## Agricultural Intelligence.

### Spring Shows.

We are informed of the following Shows to take place this Spring. We request secretaries of Agricultural Societies to inform us of the date of their exhibitions at as early a date as possible, so as to admit of publication in time to be of use to those interested:—

Fullarton, Logan, and Hibbert Agricultural Society, at Mitchell, April 2.

West Riding of York Agricultural Society, at Weston, April 23.

King Township Show and ploughing match, at Kettleby, April 22.

### Italian Pigs.

From a letter describing the animals at a recent agricultural exhibition in Italy, we copy the following:

"A few of the pigs seen here were small, rather fat, pig like cleatures; but the greater part of them were enormous, boar-like monsters, some white, some black, some very hairy, some with tusks, some without; all of them the most gaunt, long legged, diabolical looking brutes imaginable. The little round fellows were of the Cinese breed; the hairless frights were from the lovely Val d'Arno; the most formidable tusks were from Contentino and Sardinia; the most highly prized appeared to be the Tuscan Gentil, and Forestieri, black giants, almost wild, living in the woods, weighing from 600 to 700 Tuscan pounds, with long, boar like, black bristles, long tusks, and legs like stilts: bold enough to attack a traveller, and ferocious enough to give him a good deal of trouble, but furnishing pork of a superior flavor, and hams which appear to occupy a high place in the affections of Italian *gourmets*. Some of these brutes were seven feet long, without counting their long snouts, and longer tufted tails. Prince Orsini, Prince

Demidoff, and a numerous company of dukes, marquises, counts and barons, seem to have devoted their energies with especial zeal and success to the development of the porcine genus."

## Horticultural.

### Dwarf Standard Fruit Trees.

TO THE EDITOR OF THE AGRICULTURIST.—I saw a report in your valuable paper of February 1861, of a Fruit Growers' Association for Upper Canada being formed, for the purpose of collecting all the information possible, to advance the interests of fruit growers in this section of the Province.

This appears to be a step in the right direction, for as Horticulture is only in its infancy in Canada, the time cannot be hastened on too fast that every one may sit under his own vine and his own fruit tree, to enjoy the fruit of his labour.

I would like to become a member of the enterprising Fruit Growers' Association, to help along so good a work, but the distance is so great between us that I fear we will seldom meet, unless it should be through the columns of the *Agriculturist*. And these long winter evenings should be the time employed for the purpose of giving our experience to those that wish to be benefited by it.

Dr. Beadle calls on me in the February number of '61 to give some further particulars on some points than I did in my essay. This I should have done long ago, but being such a poor hand at putting my experience on paper is my only excuse. If Mr. Beadle should call on me sometime when at my plough or at work in my orchard, I could sit down and tell him much better my experience in fruit culture. But such as it is you must accept, otherwise throw it under the table. Mr. Beadle makes the remark that, I say in my essay that it is the hot sun of July or August that causes the disease I mentioned in the body of the trees. This I still believe is the first cause, followed up by the extreme heat and cold of March causing the disease to break out and fully develop itself as described in the essay, by the bark peeling from the body of the trees.

Mr. Beadle enquires our mode of trimming and cultivating the low top trees. This I think we described in our essays, which you can turn to in the July number of '59. But the advantage is not only in the protection of tender trees from the diseases before described, but also in the convenience and ease in their management, such as trimming, when you can remain on the ground to do the work, instead of climbing gorilla-like in high trees, marring and bruising every limb you step your hard nail bottomed boots upon, or poised upon a ladder, subject to falls and bruises. You often likewise wish to have the

company of your children to assist in gathering the fruit. But if a large apple should fall 10 or 15 feet from some high limb, and strike one of the little urchins on the head, it might leave him senseless on the ground, besides there is the loss of all such apples being bruised and unfit for market. But the advantage in favor of low trees is not only in the protecting of their bodies and in trimming, but also in the fruit being protected from being blown off by the winds, the convenience and ease of gathering the apples, bringing them in the barrel sound and fit for market, in keeping the plough away from tearing the upper and best roots, and the whittle trees from rubbing off the bark from the side of the trees, the trees bearing fairer fruit, and in making the labour much less in scraping and washing their trunks. Mr. Beattie recommends the bodies to be 3 or 4 feet, but I want the limbs to branch out from the ground, then snow covers up their short bodies in the winter and protects them from the frost and sun, one of the most important points. Your committee has informed the public on one very important point, in publishing the hardy kinds, all others should be abandoned. One half of the apple trees published in the American catalogue should never cross the water, or be planted this side of Toronto, for when so many fail it has a tendency to discourage men from planting. We must search for more hardy varieties, by testing new kinds that have been introduced. I shall plant out 50 or more new kinds this spring, and if I get one or two out of that number that proves hardy, I shall be well paid for my trouble. Without doubt there are more hardy kinds, and we must find them.

R. B. WERDEN.

Picton, Feb. 27th, 1832.

### On the Culture of the Vine in the Open Air.

[Read before the Hamilton Horticultural Club, by D. A. McNabb, Esq., March 4th, 1862.]

MR. PRESIDENT: SIR.—Your Secretary has assigned to me, the production of an Essay on the cultivation of the Vine "in the open air."

So important a subject he should have placed in the hands of a member more competent, and numbering, as our club does, so many practical gardeners, this would have been an easy task; such a course would also have brought out the fullest information, information that would convince any one having unoccupied ground 12 feet square, that it is his own fault or the time is not far distant when he can sit down under his own vine and enjoy the fruit thereof.

You (Mr. President) may be assured that it has puzzled my wits considering what course to pursue in framing such an essay—that it might be plain, simple, and to the point. The conclusion come to, is to give you the

course I annually pursue, convinced that that course when followed by others will produce the same results, making Western Canada, what it ought to be, a grape producing country.

Select a piece of ground having a south-east aspect, and sometime during summer trench it 2 feet deep, (if not let it be properly drained) trenching in as much top sod as can be procured from any old pasture, carefully avoiding animal manures of all kinds.

Prepare a lot of stalks 6 feet long and in number according to the quantity of vines to be planted, commence 4 feet from the walks, insert the stakes 18 inches in the ground, 12 feet between each stake and 15 feet between each row. In September or first week in October, having obtained good strong layers, (one year old) commence planting. I was going to say cut your layers back to 3 eyes, but your nurseryman will do that for you if you purchase the best varieties. Take off 2 inches of soil around each stake in a circle equal to the vine's roots to be planted, tie a vine on the south side of the stake, carefully extending the main or larger roots in straight lines from the stake, arranging the smaller ones in their natural position, with a trowel in hand commence at the extreme end of the roots and cover them with the earth taken from the circle and from the alleys, take sufficient earth to cover the roots with 4 inches of soil, pressing it firmly with the foot, which will finish the planting. I would here urge the importance of spending some little time even in minutely placing each root and rootlet in its natural position; if this is carefully done, not one vine in one hundred but will take root and establish itself before winter sets in. Nothing now remains to be done but to protect the vines with evergreen branches, and where such cannot be obtained, corn stalks or any clean dry litter will be suitable.

*Second Season.* If the vines have been covered with any kind of litter liable to decay, they should be examined shortly after the first mild weather, taking such decayed litter away and re-covering the vines with clean dry straw. During this season little requires to be done more than keeping down weeds and when ground is an object many kinds of vegetables or root crops may be put in, but if done a circle 3 feet in diameter around each vine should on no account be dug.

About the middle of May the vines should be examined, and where more than one bud has started pinch back the second to one leaf, and the one next the ground rub clean off.

During summer as the vines grow, pinch back the later branches to one leaf, tying the vines up to the stakes. About the middle of July mulch the ground around each vine with fresh stable manure 3 inches deep forming a circle around each vine 3 feet in diameter.

During the first week in October fork over the ground turning in the mulching and any *rich soil* from properly decayed manure. In November examine and Fall prune the vines, and if they have ripened 6 feet of wood a small crop of fruit could be taken from them during the third season, in which case the laterals should be cut back to the fruit buds, and the canes cut back to 3 feet, but as this is not desirable I would advise cutting back the canes to 3 buds and protecting them during winter as directed in the treatment for first season.

**Third Season.** The treatment this season will be same as the second, for vines cut back to three buds, and for those allowed to fruit the course will be pointed out in the treatment during the fourth season except in fall pruning; the canes should be cut back to 5 feet 6 inches.

**Fourth Season.** The vines having ripened canes 5 feet 6 inches, about the first of May, or earlier if the buds are pushing out tie each vine up to its stake, rub off all buds that appear on the first 10 inches of the cane from the ground, thus giving ventilation under the vines. The next two buds should be allowed to run, that is they should grow without pinching unless it be to pinch any blossoms they may show. When the remaining buds show leaves beyond the blossoms, begin at the top of the vine, and rub off all leaves except one before you come to the leaf opposite the first blossom, leaving one leaf after the last blossom, pinch back the fruit-bearing-branch. It may be here stated pinching is done with the thumb nail and forefinger, and when the summer pruning is done at the proper time—is the only scissors required during the season of summer pruning. The end of May or beginning of June the laterals will begin to push out, pinch these back leaving one leaf—and at the risk of being considered moon struck on the grape question, I would state—Each new moon indicates the proper time for pinching in the laterals, for at such a period in each month, you will find the vines pushing out new laterals which are easily pinched back to one leaf. About the first of July perform the same operation, and about the fifteenth mulch the vines with fresh stable manure 3 inches in depth and in circles 4 feet in diameter around the vines. On the first of August pinch back the laterals, and on the first of September perform the same operation for the last time during the season.

The fruit will now begin to color and during that period the vines should not be pruned.

On the first of October your grapes should be ripe, varieties requiring a longer period to mature are not worthy of cultivation around this locality and much less north of Hamilton. Consequently the crop should now be gather-

ed, and when done the ground should be forked, adding rich virgin soil as proposed in the first part of this essay.

During November the fall pruning should be done, and as there are so many styles of pruning and training the vine, I would refer to any work on the subject, that such style as pleased the fancy might be adopted. If the upright system is selected the main cane and the two leaders produced should have all laterals cut back to the fruit bud, and the leaders cut back to 5 feet each from the main stem, those leaders will give a crop the following season.

During the fifth and following years two side branches should be added annually, say 14 inches apart, that the last two would be at the top of the main stem, thus giving four branches on each side of the upright or main stem, when the vine is complete.

In after years the side branches may be worked upon the renewal system, or, as I have found suitable for this climate when the spur system failed during cold winters, the vines can be fruited upon what is known as "*old wood*" that is wood of more than one year's growth. When this system is adopted the vines should be pruned back in the fall, leaving only the upright and side branches, or what is known amongst gardeners as, the "walking stick system."

In May following when the vines are tied up to the trellises it will be found half a dozen buds have pushed at each joint. Begin at the top branches next the upright, select two of the largest buds out of the remaining ones and leaving 13 inches between each pair of buds, or as near that distance as can be arranged—thus go over all the branches.

In four to five days after this operation the buds will shew fruit blossoms, then go over the vines again, rub off the weaker one of each pair of buds, and follow up the treatment as directed for summer pruning during the fourth season.

I cannot close this essay without urging the necessity of taking every care to protect the surface roots of the vine, never using a spade nor digging of any kind during spring or summer, such a course will in a great measure prevent mildew as also increase the sources of supplying the vines with nutriment to produce and mature the fruit. You (Mr. President) will perceive in the foregoing remarks that nothing has been said in favour of making vineyards or vine borders, a receptacle for every description of filth. At the same time when earth formed from decomposed bodies, whether fish, animal or vegetable, can be obtained, no doubt such is very desirable, and when forking the ground in fall a reasonable quantity should be forked into the ground, thereby preparing a fund from which to draw a future crop of grapes, if there is an

exception to this rule the article is bones, those may be added in any quantity.

Nothing has been said regarding vines most suitable for cultivation, perhaps such is hardly within the province of this article. However, the Fruit Growers' Association have recommended the new varieties and no doubt such will be the general favourites until more suitable Canadian seedlings are produced, an event many would be pleased to see, and which may not be far distant, as many besides practical gardeners are giving this matter their attention.

As regards climate, there cannot be a doubt in the minds of those who have given this subject any thing like a fair trial, that grapes can be produced, and that in large quantities, nor is the time far distant when the shores of Lake Erie and the banks of the Detroit river will produce grapes in quantity and quality, making it at least unnecessary to import them from Kelly's Island or any other part of the United States. Now Mr. President, as you have the little I know regarding vines in the open air, I trust your Secretary will place this matter in such hands next year, that still further information will be placed before the club, information which will produce vineyards around this and other localities, making Canada as I said before a Land of Vineyards.

### Tree Wounds.

Young and vigorous trees, when injured or wounded, soon begin to heal of themselves, and in time the wound is healed or covered over by the successive layers of alburnum that each year forms and converts into wood. Very many of these wounds, however, will heal over a great deal quicker if a little care be taken in cutting away any dead wood or projecting splinters and covering over the wounded parts by some composition, such as grafting clay or grafting wax, or with a plaster of mortar made of slaked lime, sand and pulverized burnt bones, or even by a plaster of hydraulic lime.

Any one who passes through an orchard that has been subjected to the common tomahawk pruning will learn a good many lessons of nature in regards to her efforts to heal up and heal over the wounds that have been inflicted. You will see that where a limb has been cut down smoothly and level or even with the body from which it started, nature, in a year or two, has closed it up, leaving only a neat, compact cicatrix. But where a stump has been left sticking out two or three inches, you will see the efforts of nature have been in one sense, thwarted. The end of the stump still projects out dry and hard, while several layers of alburnum have been laid up one upon the other, and working inward as if endeavoring to climb over and enclose and hide it from view. If the life and

vigor of the tree continues long enough, this will be accomplished, but in many instances it fails of doing it, and the naked stump continues to project for a while as an evidence of the folly of the man who cut it off, and then the weather begins to destroy it, and decay commences. The wood rots and falls out and an unsightly hole or cavity is the result. The lesson to be learned from this is—cut limbs smoothly and even with the body from which they start, and then cover over the wound with some preparation that will prevent the decay of the wood exposed, and at the same time allow the layers of alburnum or sap-wood to be lapped on each year by the natural process.

Oftentimes these unsightly wounds can be sooner healed, by cutting down the dead wood to a level with the bark, or by a gouge, a little below, so that each successive layer of sap-wood formed after this shall roll inward and close on and over the cut instead of having to climb up, as it were, over the projecting stump before it can begin to hide the cut across the limb. A very little observation and care in these matters will soon give one an insight into the laws by which nature operates in her healing process, and by following nature, you can not only prevent much loss of her valuable labor, but can even hasten, in many instances, her labors and perfect the results desired.—*Maine Farmer.*

**WILD VINE.**—It has often asked whether wine could not be extracted from the wild grapes that grow spontaneously in many parts of Canada, and the same question may have presented itself to many of our readers who, while strolling in the vicinity of Montreal, have observed in the autumn, tempting clusters of this indigenous fruit bearing down branches of young trees, or peeping out from the high foliage of the stately denizen of the forest. Mr. de Courtenay, who has passed many years of his life in vine growing countries, lately leased Col. Sewell's villa near Cap Rouge, where he had an opportunity of becoming acquainted with the wild vine of Canada. Being familiar with the art of wine-making he succeeded in extracting from 10 lbs. of fruit produced by one vine, ten bottles of wine of a beautiful color and tasting like Bordeaux; of these, three bottles were of a first quality and seven of a second; besides five bottles of vinegar. It is said Mr. de C. intends to plant ten acres next spring with Canadian vine.

**A SPRING TART, RHUBARB.**—Does anybody doubt, or not know the desirableness of this vegetable! Then we pity him. It is one of the finest things in the world to make a pie or spring tart. Apples often give out in April or May, and those which remain are withered and tasteless. Man's stomach longs for something fresh, crisp and juicy. The pie-plant affords that very thing. It forms a connecting link in the year-

long chain of articles for pie making. Think, too of the doctor's testimony, that it is "one of the most wholesome, cooling and delicious substances that can be used for the table. For dysentery in children, it is an infallible remedy, stewed, seasoned with sugar, and eaten in any quantity with bread." We have tasted samples of fair wine made from this plant. It is also used for jellies and jams.

**Mode of culture.**—Procure a few crowns, with roots attached, and set out only one in a place. Rhubarb will live in any kind of soil, but to get large, succulent stalks; the soil must be deep and rich. Five or six plants are enough for an ordinary family. Lay off a bed 20 feet long by 4 wide. Remove the top soil; break up and manure the subsoil heavily, and then return the top spit to its place. This last should be enriched with a light dressing of old manure; and if the land is stiff clay, a little sand should be worked in. Then set out the crowns by a line, four feet asunder, leaving the plump, pinkish beds an inch or two below the surface. This work may be done in the Fall or early in Spring. New roots will soon form, and the growth will rejoice the eyes of the planter.

The after culture is very simple. Keep the ground free from weeds. Pluck no leaves the first year. In the Fall, put a peck or more of coarse manure around each plant; this will protect the roots and furnish nutriment for the next year's growth. In the second summer the leaves may be plucked in moderation, and after that quite freely. Let the plants, however, have their autumnal dressing, to be forked into the soil the following Spring. In our own grounds, we have pursued this course several years; and now the stalks and leaves of our plants are so magnificent, we are often asked the name of our new and improved varieties. We uniformly reply by pointing to the manure heap.

**Forcing.**—If any one wants to get a very early tart or pie, he should, towards the end of this month, set a barrel or rough box—headless and bottomless—over the crowns of several early plants, and surrounded the same with fresh manure from the horse stable. Put a few forkfulls inside of the barrel, and a bushel or more outside. This will soon generate a local climate of 50° or 60°, and give the plants a start, while those not so treated are yet asleep. The barrels should be kept nearly or quite covered for ten days, and then gradually opened as the season and all plants progress. Add a little fresh manure outside the barrel after the first week. As soon as the other plants are fit to cut, the forced ones should be uncovered and allowed to rest.—*American Agriculturist*.

**VENTILATION OF FORCED PLANTS.**—Probably, the most delicate of all the requisite operations is the proper regulation of the supply of moisture to root and branch. A certain amount of moisture is essential to the health of all plants,

and this amount varies in different cases; but with few exceptions, certainly as a rule in the case of flowering plants, this must not approach to the state of wetness. Formerly it was thought that these plant cases, or Wardian cases, required to be kept constantly closed, and then the plants were continually in a vapour bath, and as a consequence, they were as continually "damping off." It is now better understood that ventilation is absolutely necessary to the growth of plants in glass cases; and one object of ventilation is to regulate the atmospheric moisture by carrying off the excess, which would cause the flowers and leaves, and, in extreme cases, the stem itself, to rot. Experience alone, but experience soon to be gained by an intelligent and watchful eye, can teach a safe lesson as to how much moisture is necessary in particular instances. Probably, the safest rule is to allow the plants only the smallest quantity of water which will keep them from drooping, and in winter, at least, it will be found that within the shelter of the glazed covering the soil will dry so slowly that weeks may intervene between the waterings, especially if the pots are plunged in some such material as dry sand, which is desirable. When artificial heat is employed, as when bulbs are forced into bloom, a greater amount of moisture will of course become necessary.

**KEEPING CELERY IN WINTER.**—A correspondent of the *American Agriculturist* says:—I carefully lifted my celery with as much earth as would adhere to the roots, and set the plants close together in the milk trough in my spring-house, and at once put in and have maintained about 6 inches water in the trough. The celery shows as much vigor of growth now (Jan. 15), as before transplanting, being much larger now than when it was dug up, bleached nicely, and the new growth is very fine and crisp.

## Domestic.

**HINTS FOR CLEAR SPARROWING.**—Collars, under sleeves, or handkerchiefs, of very fine muslin or lace, will not bear much squeezing or rubbing when washed. They can be made perfectly white and clean without either, or by the following process:—Rinse them carefully through clean water, then soap them well with white soap, place flat in dish or saucer, and cover with water; place them in the sun. Let them remain two or three days, changing the water frequently, and turning them. Once every day take them out, rinse carefully, soap and place in fresh water. The operation is a tedious and rather troublesome one, but the finest embroidery or lace comes out perfectly white, and is not worn at all, where, in common washing, it would be very apt to tear, when they are white, rinse and starch in the usual way.—*German town Telegraph*.

## Veterinary.

### Pleuro-Pneumonia.

Report of a committee appointed by the Massachusetts Board of Agriculture to enquire into the state of this destructive disease among horned cattle, published in a recent number of the *Boston Cultivator*.]

The undersigned, a Committee appointed by the Board of Agriculture to prepare a statement of facts for publication in relation to the cattle disease, would respectfully report that—

Having good reason to fear that the disease known as pleuro-pneumonia (so fatal in its ravages among the neat stock of North Brookfield and vicinity in the years 1859 and 1860) has again made its appearance in several towns in the county of Norfolk, they feel it the duty of this Board to warn the farmers and others, owners of neat stock in the Commonwealth, that the time has arrived for them to take every precaution to prevent the spread of this scourge; and in view of its contagious nature they would urge the necessity of the greatest care being taken by all interested in purchasing or permitting strange cattle to come in contact with their herds.

The disease now claiming our attention made its appearance in the town of Quincy last April, breaking out in two herds nearly simultaneously. Eight animals from one of the herds were sold to a person in Randolph, in the month of September, for \$85 for the lot. One of these animals died before reaching the home of the owner and three months shortly after. The other four have been lost sight of. One herd in Milton, and also one herd in Dorchester, have been affected for some months. Four animals from one of these herds, which had been sick during the summer of last year, but had apparently recovered, were taken to Brighton in the fall and sold. Four of the other herd have since died or been killed—all presenting a seriously diseased appearance. On examination by the veterinarians conversant with the Brookfield complaint, they pronounce it identical, so far as they could judge. There are four or five animals still left of this herd, some of which are either sick or showing symptoms of contagion. There are also other cases which have not been examined—the Selectmen of the towns waiting the action of the Legislature in passing a law authorizing a new commission. The law has now been passed, and the commissioners appointed, and we would respectfully urge upon the gentlemen composing that commission, the great importance of immediate measures to investigate the disease, and if necessary applying the remedies placed by the law in their hands, that the ravages of this fearful pest (which there is little

doubt is identical with the Brookfield disease, and which can be traced to that neighborhood,) may be stayed.

There being doubters in the community as to the existence of contagious pleuro-pneumonia, earnest attention is called to the thorough and convincing report of the first Board of Commissioners, with accompanying documents, published in the report of the Secretary of the Board of Agriculture for 1860.

We believe that no person, however prejudiced he may have been, who has been present at the examination of affected animals, has failed to become convinced of the contagiousness of this disease; and it would seem impossible that any one can doubt this fact who will take the trouble to examine the various reports that have been made in Europe and in this country on the subject.

HENRY H. PETERS, of Southborough,  
PHINEAS STEDMAN, of Chicopee,  
FREENAN WALKER, of No. Brookfield,

Committee.

Boston, Feb. 27th, 1862.

## Miscellaneous.

### A Chapter on Clouds.

(FROM THE BOSTON CULTIVATOR.)

The study of clouds is interesting and useful. A knowledge of their changes, the phenomena which they present, the endless variety of shape and size which they assume, their formation and dissipation, their varying colors, all combined to render them objects worthy of investigation. They are intimately connected with the human affairs of the world. Their appearance in the morning influences the business and pleasures of the day; their changes during the day control the plans and often frustrate the wishes of man; their character at night is consulted in arranging the operations of the following day. The business of all classes is influenced more or less by the changing clouds. The farmer daily observes them and plans his work according to their indications. It is of the utmost importance that he should understand their character, the laws which govern their formation and dissipation, and the beneficent purposes which they continually accomplish in their varied movements.

A classification of clouds was made by Luke Howard in 1802. He divided them into three primary classes; cirrus, cumulus and stratus, with intermediate forms passing into one another under the names of cirro-cumulus, cirro-stratus, cumulo-stratus and a composite form, resulting from a blending of the others, under the name of nimbus. Cirrus clouds appear like parallel fibres or loose hairs extending in any or all directions. When the streamers point upward the clouds are falling and rain may soon

be expected; but when they point downward, fair weather is at hand. Cumulus clouds are those convex or rolling or globular masses which resemble volumes of smoke, or huge mountains piled upon one another. When they are fleecy and sail against the wind apparently or in an upper current, they foreshow rain; when they come up with the wind and their outline is clearly defined fair weather is near. If they diminish in size near sunset, the following day will be fair; if they increase, it will be foul. Stratus clouds are those which fly along near the surface of the earth, widely extended, horizontal sheets. They are thin and misty, and such arise from beds of moisture in low lands soon after sunset. The cumulo-stratus clouds are those which assume all kinds of gigantic forms; such as vast towers, piles of rocks, &c. In the vicinity of the White Mountains, their appearance is wild and romantic. Travellers have noticed the strange sublimity which hangs around the clouds in this region. The majestic career of these vast mountain piles urged on by the winds and electric forces just before a storm is grand and imposing. Cirro-cumulus clouds are heavy masses, edged with long streaks called "mares' tails." They foretell dry, hot weather. When combined with the cirro stratus form, which is called a "mackerel sky," they always indicate rain and wind. Nimbus clouds are rain-clouds, and are without any definite outline.

Clouds are formed by the condensation of the invisible moisture in the air by colder currents and are wafted in masses from one region to another by the force of winds. They give the earth a sombre hue. I verily believe there is more scolding about cloudy days than all other troubles combined.

Clouds are transitory visitors. They come on the "wings of the wind," arrayed in fantastic shapes. Their forms greet us with seeming smiles as they vanish in "dissolving views." It is a pleasant thought to imagine them chariots of angels. On Olivet's sacred mount a cloud received the Holy One and bore him away from the gaze of the wondering disciples. They parted over the Jordan and out from the azure depths of heaven came the baptismal words "This is my beloved Son." The holy records are replete with imagery of which clouds are the medium. My thoughts are often attracted to the pleasing phenomena of the canopied heavens and the material uses of the clouds to man.

Clouds are dissipated by warm, dry currents of air which absorb and render them invisible. Some of their notions are influenced by electrical attractions and repulsions. The friction produced causes the electricity in the clouds, which may be called the manufactories where the winds grind it out to supply the never-ceasing demands of Nature. The electrical displays from the thunder cloud have been witnessed

since the earliest ages; and the investigations of science have thrown a halo of interest around the "frowning barriers of heaven," whose glittering artillery was once regarded with fear and trembling, as the expressions of the Divine displeasure; but now transfused with a brighter glow as they have been brought down to the earth and tamed for the service of man.

Who has not beheld the indescribable glories of our New-England sunsets? What illimitable fields of cloud scenery! What exquisite pencillings they display! What displays of magnificence and splendor! If beheld but once in a century men would gaze, as upon the very throne of the Eternal. And yet these scenes of beauty, so unspeakably fair, image a higher beauty which no man can look upon and live.

The shaded tints of purple which are impressed upon the irregular edges and surfaces of clouds are caused by the red rays of sunset, which, being the least refrangible are the last to disappear. They indicate fair weather, for they show that the vapor is not condensed into clouds by the cold of the evening. Our Saviour referred to this prognostic in the following words: "When it is evening ye say it will be fair weather for the sky is red." Their appearance in the morning denotes a wet or a fair day. Hence our Saviour's observations, "In the morning ye say it will be foul weather to day, for the sky is red and lowering."

The clouds are the great store-houses of rain, the uses of which are so apparent, I need not refer to them. The arrangement for its inexhaustible supply in proper quantities and at the right time, through the medium of the clouds, excites our wonder, admiration and gratitude. Again they temper the heat of the sun's rays and prevent a too rapid evaporation of the moisture from the earth's surface. They also arrest the radiation of heat from the earth; in consequence its surface remains warmer than in clear weather; hence the reason why there are no frosts in cloudy nights. What splendid protectors to the grain fields and fruit orchards are the clouds! How admirably do they wrap up the earth as in swaddling clothes, disarming the frost of its power! They mitigate the severity of a northern winter, and moderate the excessive heat of summer. Without them the earth would be a Sahara. Vegetation would die; springs would dry up; rivers cease to flow; famine and death would hold undisputed sway and the "earth would melt with fervent heat."

WM. A. WHITE.

DESCENT OF THE EAGLE.—In *Forest Creatures* by Charles Boner, we have an account of the remarkable power possessed by the eagle of instantaneously arresting himself while dropping through the air at a certain spot, with folded wings, even when descending from a height of 3,000 or 4,000 feet. "When circling so high up that he sho

but as a dot, he will suddenly close both wings, and, falling like an aerolite, pass through the intervening space in a few seconds of time. With a burst his broad pinions are again unfolded; his downward progress is arrested, and he sweeps away horizontally, smoothly, and without effort. He has been seen to do this when carrying a sheep of twenty-six pounds weight in his talons; and from so giddy a height that both the eagle and his booty were not larger than a sparrow. It was directly over a wall of rock in which the eyrie was built; and while the speck in the clouds was being examined, and doubts entertained as to the possibility of its being the eagle, down he came headlong, every instant increasing in size, when in passing the precipice, out flew his mighty wings; the sheep was flung into the nest, and on the magnificent creature moved, calmly and unflurried, as a bark sails gently down the stream of a river."

**AN ALPINE LAND SLIP.**—The Steinberg cliff, a rocky wall of several millions of cubic fathoms, with all the forest upon it, and the nagelfluh wall of the "Gemeinde Marcht" sinking like a terrace more than 100 feet below, had given way. This was the signal for universal destruction, for then began a tragedy which can be compared to no other phenomenon for its fearful sublimity. In the wildest confusion blocks of rock and splinters of stone, mud and turf, foliage and trees, sometimes whirled up into the air, sometimes, enveloped in clouds of dust, chased each other over the mountain shoulders of the Vale of Gordan. The chaotic fall of the vast masses, the speed of their descent, the universal confusion, increased every moment. Mountain blocks as big as houses, with pines fixed to them, hurried, as if slung by a demon's fist, with three bounds like flying birds, high through the air. Other masses of rock ricocheted like shots from a giant cannonade, striking from time to time only to bound up again into the air. Others were crushed by their companions on their path, and splattered like white-hot iron rods shooting out sparks under the hammer. It was a scene from the Titan's battle of Greek mythology.—*Berlepsch's Alps*.

**AN ELEPHANTINE ACTOR.**—Sir Emerson Tennent, in his Natural History of Ceylon, says the elephant occasionally feigns death in order to regain its freedom. Of a recent captive he writes—"It was led from the corral as usual between two tame ones, and had already proceeded far towards its destination, when, night closing in, and the torches being lighted, it refused to go on, and finally sank to the ground, apparently lifeless. Mr. Cribbs ordered the fastenings to be removed from its legs, and when all attempts to raise it had failed, so convinced was he that it was dead, that he ordered the ropes to be taken off and the carcass abandoned. While this was being done, he and a gentleman by

whom he was accompanied leaned against the body to rest. They had scarcely taken their departure and proceeded a few yards, when to their astonishment the elephant rose with the utmost alacrity, and fled towards the jungle, screaming at the top of its voice, its cries being audible long after it had disappeared in the shades of the forest."

**A WORD ABOUT SERPENTS.**—There is another little serpent, says our old friend, who is painfully active in his movements, and a master of the science of projectile s. He springs upon his prey from beneath shrubs, &c., after having turned himself rapidly round and round upon the ground to obtain that rotatory motion for his flight which alone insures accuracy of aim. He is quite a Whitworth in his way, is this little serpent, the *Acontia*; and brings down his men at twenty cubits distance. The *Paubera* secures his prey with a hook, which is fastened to the end of his tail. He swallows oxen alive and entire, and consequently suffers severely from indigestion on account of the bones. Our old friends the asps, vipers, boas, anacondas, cobras and rattlesnakes, figure in this strange company, and we have many novelties concerning their nature and value. You would not imagine, now, that from vipers "many noble medicines are prepared," and that "a wine from their flesh is singular in consumptive, leporous, and scorbutic cases," or that "they afford also a volatile salt, the most generous cordial in nature." Great is the power of simple things. If ever dear reader, you meet a rattlesnake, don't run away, but get a branch of wild penny-royal; then, having fastened it to the end of a stick, present it to the creature's nose, and if it be only of the family, one of which was so dealt with by Captain Silas Taylor, in the year 1657, it will turn and wriggle, labouring hard to avoid the potent herb, and die in less than half an hour from its mere scent.—*Once a Week*.

**FAIRY RINGS.**—An accidental circumstance occurred to me on a journey to visit the far-famed and beautiful monastery of Batalha, in Portugal. On our road we were overtaken by one of those tremendous thunder-storms incident to hot climates, and which bear no comparison to the slight movements in the elements of our colder atmosphere. Whilst taking shelter from the fury of the storm, the forked lightning struck several objects not far from us. Soon afterwards I observed several rings of smoke and gas floating slowly in the air, which, preserving their circular form, enlarged and diminished alternately until they ultimately settled in that form on the sward before us. In a day or two afterwards, on passing the same spot, I observed on the sward several rings, densely green, two or three inches wide; the grass of which (circumferences or rings) had grown full an inch in that short time, and fungi were beginning to make their appearance. There must have been some very fertilizing property in the gas; and it has struck me that the same may

take place in the new experiments for promoting vegetation by electric rods and wires. In the country I have always observed that these rings make their appearance after thunderstorms; and I never yet met with a better solution of the phenomenon than that which accident afforded to me, as above related. Nor have I ever seen any one who had seen a fungus, or fungi, spring up, and a ring to radiate from it. But I have observed these rings to last for two or three years, and to enlarge, in the course of time, which is not sufficient to establish the truth of the mere theory, that these rings are caused by spawn that radiates from a common centre.—*Gardners' Chronicle*.

**INFLUENCE OF ELECTRICITY.**—The injurious effect of a sudden increase of electricity is very strongly marked upon the young of all animals, the hurtful influence being in proportion to the growth of the victim. Eggs are peculiarly susceptible to the influence of electricity, and, even when the chick is partially matured, are often killed by a passing thunderstorm. In climates where thunderstorms are frequent and violent, as in the lands which are inhabited by the humming-birds, it is needful that the eggs should be protected from the deadly influence, and we accordingly find that the nests are oval or rounded in shape, and are made of substances which are bad conductors of electricity.—*Roughledge's Illustrated Natural History*.

**PEAS WITH POTATOES.**—In a letter in the *Agricultural Gazette*, an English paper states that a single pea inserted into each piece of potato that is planted, will produce a large crop of peas, and tend to check disease in the potato. It is a practice with some to plant peas with potatoes, here. The potato stems answer a good purpose for the pea vines to run upon.

**ONE HUNDRED YEARS AGO.**—In the last part of the eighteenth century appeared, nearly at the same time, the edicts of Turgot for the enfranchisement of labor, and the book of Adam Smith on the nature and the cause of wealth. At nearly the same epoch, Lavoisier laid the foundation of the discoveries which were to transform chemistry; Watt took his first patent for his perfection of the steam engine, and Arkwright obtained a patent for spinning by rolls. These events contain the germ of the principle, and of the means adopted by modern industry. Modern chemistry gave birth to numerous industrial processes; the perfected steam engine furnished a motive force applicable to the most varied mechanisms; mechanical spinning and weaving replaced the ancient mode of manufacturing tissues and multiplied the production of manual labor; finally, the ideas until that time dominant gave place to notions more just and more exact on the nature of wealth and on the means of developing it.

**THE FARMERS AND THE WAR.**—This country would be able to support a very large number of fighting men through an indefinite period of

time if the peaceful industry of the community was directed to this end. It would simply be necessary to divert the labors of those who are no engaged in making superfluous luxuries to the production of food and clothing. This diversion of labor will be gradually effected by a decline in the price of luxuries and an advance in those of the necessities of life. This already begins to be felt; while works of art, books, jewelry, &c., are of a very slow sale, the coarser styles of woollen cloths and satinets have advanced some 30 per cent in price in such colors as are adapted for military purposes. If the community is intelligent, they will anticipate this change in the in the market demand for articles, and will, by a prudent forecast, save us from a scarcity of products absolutely essential to existence. This applies with especial force to farmers. Let them sow their seeds with perfect confidence that there will be a certain demand for their crops, which will bring better prices than in preceding years. Above all things, let us not have the horrors of famine added to the trials of war.—*Scientific American*.

### Editorial Notices, &c.

THE BRITISH REVIEWS FOR JANUARY, 1862.—  
Republished by L. Scott & Co., 54 Gold St.,  
New York.

We have received through Mr. Rowsell, Bookseller of this city, copies of the American Edition of the *Quarterly, Edinburgh, Westminster, & North British Reviews*, commencing the volumes of the present year; also *Blackwood's Magazine* for January and February; for which we take this opportunity of thanking the attentive and enterprising publishers. Referring to the influence of these Reprints on the American mind one of their own critics well observes:—

"The best talent in England is employed upon them, and although the circulation of some of them, is actually less in Great Britain than in the United States, they are to a certain extent the organs of the advanced opinions within their several spheres of influence, corresponding in some degree with the gradations of American sentiment in religion, philosophy, and statesmanship. This fact accounts in some measure for the daily increasing circulation of the British reprints in the United States, and the estimation in which they are held in enlightened and educated circles here. They likewise sound a depth of profound thought comparatively unknown to our literature, and pursue abstract and practical investigations to a point seldom attempted by American critics and reviewers. This quality renders them the more valuable to us, as study which develops the radical diversity in the mental methods of John Bull and Brother Jonathan.

—a study which cannot be closely pursued without a modification to an extent of some of our rapid Yankee characteristics. There is no doubt that the imperceptible mingling of the two nationalities now going on is effecting a favorable result upon both, and nothing will tend to increase the ameliorating process like a free interchange of sentiment through the current literature of Great Britain and the United States. The republication and extensive circulation of the British Reviews in this country has to a great extent effected this object, and through their columns a mutual interest in the affairs of both countries has sprung up and ripened into important and healthy results."

In *British America* how desirable it is that these recognized standards of British Literature, Science and Politics should be extensively known; and we are therefore glad to learn that their circulation of late has been much increased both in Canada and the other Provinces. The views entertained by British writers on the civil war that is now unhappily afflicting the great neighboring Republic, may be readily learnt from these periodicals, which correctly represent the opinions of the various leading parties of the empire. It should be borne in mind that these are not pirated editions; Messrs. Scott & Co., have arrangements with the British publishers for advanced sheets, which enable them to reproduce these invaluable periodicals and place them in the hands of their numerous subscribers throughout this vast continent within two or three weeks after their publication in Britain, and that too, for one third of the original price!

The present is a favourable time to commence subscribing, as the new volumes for 1862 began with the January numbers. The terms per annum for any one of the four Reviews, or Blackwood, are \$3. For any two, \$5; and for the whole only \$10; thus placing the recognised exponents of British learning and statesmanship within the reach of individuals interested in such matters either singly or by clubbing.

### Imported Thorough Bred Cattle FOR SALE.

THE SUBSCRIBER OFFERS FOR SALE, the whole of his lately imported herd of improved Short horns. Full pedigree for each, authenticated by reference to Coates's English Herd Book.

G. W. PHILLIPS,  
Ogdensburg, N. Y.

## Fresh Garden, Field, & Flower Seeds.

FOR SPRING SOWING.

JAMES FLEMING & Co., Seedsmen to the Agricultural Association of Upper Canada, beg to inform their friends, and the Farmers of Canada generally, that their stock of Fresh Seeds is now complete and very extensive, embracing almost every kind of seed suitable for the country. The stock of Agricultural Seeds is large and well selected. The vitality of each sort is carefully tested, and their genuineness may be fully relied upon. A large stock of Peas, Timothy, and Clover:

Spring Tares,  
" Wheat,  
Black and White Oats.  
Swede Turnips, Purple top.  
" " Green top.  
" " Laing's Improved.  
" " Skirving's Improved.  
White Globe Turnip.  
Yellow Aberdeen "  
" Altringham "  
Waite's Eclipse Turnip.  
Stubble or Six Weeks "  
Mangel, Long Red.  
" Long Yellow.  
" Yellow Globe.  
" Red Globe.  
" New Olive Shaped.  
Sugar Beet.  
Field Peas, several varieties.  
Marrowfats, " "  
Barley, two and four rowed.  
Buckwheat.  
Indian Corn, several varieties.  
Alsike and White Clover.  
American Orchard Grass,  
Kentucky Blue Grass.  
English Rye Grass.  
French Lucern.  
Cow and Rib Grass.  
Carrot, White Belgian.  
" Long Orange.  
" Altringham.  
Parsnip, Hollow Crowned.  
&c., &c., &c.

Also a full and general assortment of all kinds of Garden Seeds: a Catalogue of which, with directions for sowing, can be had on application. Agricultural Societies ordering Seeds, will be supplied on liberal terms. Country Merchants supplied with complete assortments of Garden Seeds on Commission, neatly put up in boxes of 200 papers each, for retailing at five cents a paper. Also a large assortment of Flower Seeds, embracing the novelties of the season.

No. 126 Yonge Street, Toronto.

March, 1862.

**FOR SALE.**

A LOT of thorough bred improved Berkshire Pigs of various ages.

R. L. DENISON,

Dover Court.

Toronto, Aug., 1861.

**BOARD OF AGRICULTURE.**

THE Office of the Board of Agriculture has been removed to 188 King Street West, a few doors from the late location adjoining the Government House. Agriculturists and any others who may be so disposed are invited to call and examine the Library, &c., when convenient.

Toronto, 1861.

HUGH C. THOMSON,  
Secretary.

**of Co-Partnership.**

THE Undersigned have entered into Partnership as Seedsmen and dealers in all kinds of Agricultural and Horticultural Implements, under the firm of James Fleming & Co.

JAMES FLEMING,  
GEORGE W. BUCKLAND.

**NOTICE.**

JAMES FLEMING & CO., Seedsmen to the Agricultural Association of Upper Canada will carry on the above business, wholesale and Retail, at 126 Yonge-st., 4 doors North of Adelaide-street, until next July, when they will remove to the new Agricultural Hall, at the corner of Queen and Yonge streets.

JAMES FLEMING will continue the business of Retail Seedsmen and Florist at his old stand, 350 Yonge-street.

Toronto, January 1st, 1861.

**FOR SALE.**

AT

WOODHILL, WATERDOWN P. O.

MR. FERGUSSON expects to have several *pure Durham bull calves* to dispose of next Spring, 1862, not intending to raise any this season. These calves will be all of the well known *DUCHESS* tribe, and will be put on the G. W. R. R. at six weeks old for eighty dollars each.

N. B.—First come, first served.

Waterdown, Nov. 14, 1861.

4-t.

**THOROUGH BRED STOCK FOR SALE.**

THE SUBSCRIBER has for Sale Durham and Galloway Cattle, male and female. Leicester, Cotswold, and Lincolnshire Sheep, male and female.

January 1, 1862.

JOHN SNELL,

tf.

Edmonton, P. O., C. W.

## VETERINARY SURGEON.

**A**NDREW SMITH, Licentiate of the Edinburgh Veterinary College, and by appointment, Veterinary Surgeon to the Board of Agriculture of Upper Canada, respectfully announces that he has obtained those stables and part of the premises heretofore occupied by John Worthington, Esq., situated corner of Bay and Temperance streets, and which are being fitted up as a *Veterinary Infirmary*.

Medicines for Horses and Cattle always on hand. Horses examined as to soundness, &c.

Veterinary Establishment, Corner of Bay and Temperance Sts.

Toronto, January 22nd, 1862.

## FOR SALE.

A FEW PURE-BRED SOUTH-DOWN RAMS  
and Ewe Lambs, from

## IMPORTED STOCK,

Selected from the Best Flock-dealers in Dorset,  
Wilts, and Hants.

The Subscriber will Warrant these Lambs to produce as much Wool and Mutton, and of equal Quality, as those of Jonas Webb, or any other Flock of the same kind and number in England.

JOHN SPENCER,  
Brooklin, Post Office,  
Ontario County C. W.

Oct. 12th, 1861.

THE  
JOURNAL OF THE BOARD OF ARTS  
AND MANUFACTURES,  
FOR UPPER CANADA,

Is Published on the first of every Month,

**A**T \$1 per annum for single copies, or to clubs of ten or more at 75 cents. per copy; to members of Mechanics' Institutes, and of Literary, Scientific, and Agricultural Societies, through their Secretary or other officer, 50 cents per annum per copy.

Subscriptions payable in advance.

Printed for the Board of Arts and Manufactures for Upper Canada, by W. C. CHEWETT & Co.,  
King Street East, Toronto.

## FOR SALE.

**A** LOT of thorough bred Essex Pigs,—bred from recently imported 1st prize animals and who have this season taken premiums at both Township, County, and Provincial Exhibition.

JAMES COWAN.

Clochmhor, Galt P. O., Oct. 19, 1861.

No. 7.

### The Cultivation and Preparation of Flax.

(Continued from page 167.)

*Conversion of the Straw into prepared Fibre.*—The first operation is that of separating the seeds from the stems, a process termed “ripping,” which is effected by drawing the heads of the sheaves through a stout ripple, or comb, firmly fixed on the centre of a bench or form, which allows of two persons to work at the same time. This is best performed when the flax is fresh from the field, but when the straw is dry and rigid by keeping, the seed-bolls are best separated by a “beater,” which prevents the fibre from being broken and injured, when used with care.

Various processes have been adopted for reducing the straw to prepared fibre, but they may all be classed under two heads; the *mechanical*, in which the operations are conducted in a *dry* state, and the *chemical*, in which moisture and temperature are more or less necessary. In the first the object is obtained by the different parts being mechanically separated from each other without any changes being effected; in the latter, the plant itself is disintegrated, either by the action of fermentation, which destroys, or of some solvent, which merely abstracts the cementing matter by which the several parts of the straw are held together. The dry or mechanical method can only be applied with advantage in case of inferior straw, and for coarse goods not requiring to be bleached, as canvas,

rick covers, rope-yarns, &c. The *chemical* or wet process “is effected in three different ways, in each a different principle is involved. The *first* is that where the separation is effected by simple fermentation, known as “steeping;” the *second*, where it is due to the abstraction of the nitrogenized extractive compound by the agency of chemical solvents; the *third*, where simply water, either heated or in the shape of steam, is made use of for the same purpose.’ In the first, which is the oldest and still the most prevalent system, a destructive fermentation is carried on, either slowly or rapidly, according to the temperature of the water in which it is steeped, at the expense of the extractive matter of the plant, and offensive and noxious gases are generated; in the second, this matter is removed by the aid of chemical ingredients, which are costly, and never altogether efficient in their action; while, by the third, the separation may be effected without any chemical changes taking place in the composition of the plant, and all its several parts be left in an available condition.

The following description of the modes of preparing flax for manufacturing purposes as practised in the British Islands is taken from a Report of Mr. A. Kirkwood, who was deputed by the Canadian Government in 1854 to visit Europe with a view of ascertaining the most approved methods of growing and preparing this invaluable plant. Some subsequent improvements in matters of detail have been made,

but it is believed that the leading principles, remain substantially the same :—

Flax-straw with the seed on is purchased from the farmer at a fixed rate per ton; it is sometimes sold out of stock, but it is better if it has been stacked for a short time, as there is less risk of heating when built in large stacks, and also less loss by drying. Some large concerns have lost from the last item alone as much as £300 per annum.

Each farmer's straw is kept separate from others in its different stages, viz :—Stacking, seeding, steeping, drying, and scutching. By this means its loss by seeding, and the yield of fibre can be more readily determined, affording to the purchaser a criterion for his guidance in future years.

Round stacks with ventilators in the centre are preferred, the whole resting on cast metal pillars (Fig. 1) with inverted dish shaped caps of the same material. These prevent injury being done to the straw, by rats or mice.

All extensive factories of the kind under consideration have rail-roads for trucks radiating from them in different directions. Among these one to the stack yard, with a view to the easy and rapid carriage of the straw to the seeding-house.

Fig. 1.

Fig. 2.

It is again weighed and the loss in stack ascertained. The seed is taken off by means of cast iron rollers, (Fig. 2) making twelve revolutions per minute. They are solid, nineteen inches in length and twelve in diameter. A handful of straw is taken by the operator and the seed end passed between the rollers at A, the root end being firmly held by the hand.—This is repeated three or four times, and the bolls are sufficiently crushed. The roller B, is free to move upwards.

A different apparatus for seeding has been described on a previous page.

Seeding in winter is a constant operation.—The greater the quantity sold to farmers for sowing the greater is the profit, as the price for crushing purposes is less.

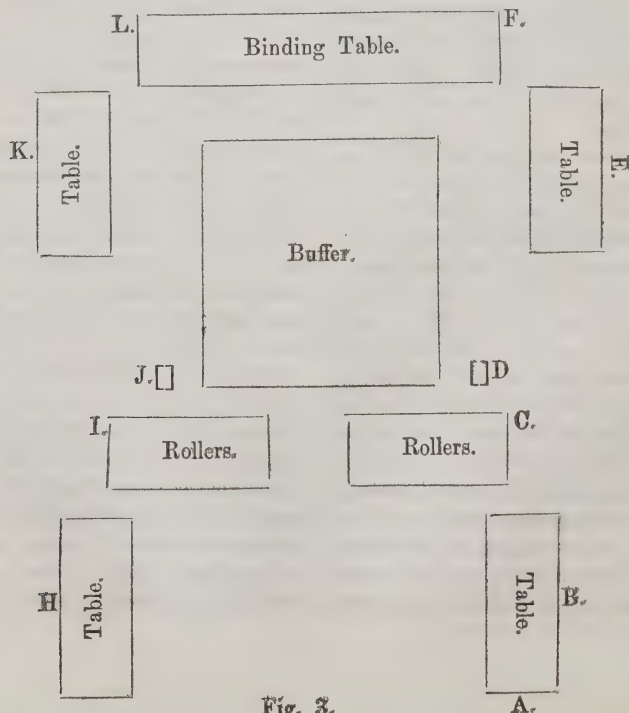

Fig. 3.

In factories working twelve vats, two sets of seeding rollers will be required. A ground plan of arranging these and their accompaniments is represented by Fig. 3.

A little girl, A, opens the bundles of straw, passes them to B, who divides them and gives them to the seeder C. She places them on the square table from which they are taken by D, whose duty it is to pass the seed end through the buffing machine to separate the chaff.

This is a covered cylinder, three feet in diameter, and five feet in length, making one hundred and thirty revolutions per minute. On its circumference are six rows of wooden teeth, each twelve inches long, and distant from each other one a-half inches at base.

E, either straightens the root end by hand, or

puts a loose bundle in the machine for the purpose, from which it is taken by F, and bound.

The same routine is performed on the opposite side.

If more straw is seeded than is required for steeping, it is re-stacked.

Six tons of straw with the seed on may be done by two sets of rollers per day, at a cost of two shillings and ten pence per ton.

All the seed, chaff, and uncrushed bolls that come from the seeding rollers are passed through a machine, (Fig. 4,) having two sieves. The wires in sieve A, are about  $\frac{5}{16}$  of an inch apart, those in sieve C,  $\frac{1}{16}$  of an inch.

The flax-seed, chaff, and sand fall through it, upon the shuffle-board B, which delivers them to

Fig. 4.

C, through which all the seed and fine dust fall at E. The chaff passes over to the floor at F. A cam gives motion to it, causing it to rise and fall with a jerk. A horizontal motion is given to B by the crank-rod F, worked by the pinion G. C has a motion similar to A.

The uncrushed bolls separated by the sieve A,

are either crushed, or sold to farmers for feeding purposes at one shilling and two pence per bushel. The chaff is worth from two pence to four pence per bushel.

An arrangement is made at E, (Fig. 4,) by which elevators raise the seed to the hopper A, (Fig. 5.)

Fig. 5.

In this side view of the fanners are represented two shuffle-boards (B, D,) having a horizon-

tal motion from cranks, and two sieves (C, E) moved by cams. The sieve C is made of par

let wires, and E of perforated zinc. The blast from the fanners passes at F as the seed drops from D to E.

The seed is bagged at G, or spread on the floor.

The average yield of clean seed from a ton of unthrashed straw is about five bushels, of chaff, eighteen, and of bolls, three bushels.

Other machinery for the same purposes as those here treated, may be found in operation.

Steeping is the next step, or it may be that some prefer steaming. Up to this point the processes are common to both systems, but now the similarity ceases.

Fig. 6.

I will notice here, the method of Schenck.—Fig. 6 is a ground plan of six vats, showing also, the steam-pipe and water-pipe. Water is admitted by this pipe from a reservoir or tank on a higher level than the surface of the vats. This is heated by steam, to any required temperature.

Vats (Fig. 7,) are generally made of 2½ inch plank, 6 ft. 8 in. in depth, 9 ft. 6 in. in transverse diameter, and 13 ft. 6 in. in longitudinal diameter. They have false bottoms covering the steam coil: and covers represented as put together by Fig. 8.

Fig. 7.

To fill a vat, three or four beets of flax-straw are placed on their side, in one end. A row of beets is then put across the vat in the direction of its shorter diameter, and resting on their root ends, in a somewhat inclining position.—Another row, but inverted, is placed against this, and so on till the opposite end of the vat is reached. The division floor is then put on, and a like quantity of flax-straw placed on top. The cover is then firmly secured in its place.

Fig. 8.

We have seen that water can be admitted at any required temperature. That at present most desirable, is 90 degrees Fah.

| A   |    | ° 267 |    |    |    |
|-----|----|-------|----|----|----|
| ApL | 6  | 9     | 12 | 3  | 6  |
| 15  |    |       |    |    | 90 |
| 16  | 90 | 90    | 89 | 89 | 89 |
| 17  | 90 | 90    | 89 | 89 | 89 |
| 18  | 88 | 88    | 88 | 87 | 87 |

Fig. 9.

That the minute attention paid in some establishments, to this particular part of the process may be seen, I give a form of board in use, (Fig. 9,) one of which is placed opposite each vat.

A, tells where the flax was grown: The number 267 indicates the number of times this individual vat has been filled since the beginning of the year; 15, &c., in the margin denote the days of the month, and the figures opposite are the temperatures, which are taken and recorded every three hours, as at 6, 9, 12 o'clock, &c.

We will suppose that water at 90 degrees has covered the straw in the vat, and that the supply has been checked. Fermentation ensues, and carbonic gas begins to be evolved four hours afterwards. The flax stems-well, and water is forced into the overflow pipe. A white froth

Fig. 10.

and scum now appear on the surface, and gather as the evolution of gas increases. The water is changed in color and taste. Hydrogen must also escape, as the application of a light ignites the whole surface of the water in the vat.

Sufficient water at 90 degrees is now admitted, to cause an overflow, which removes impurities, and leaves the flax in a fairer condition.

If the temperature falls too low, steam is easily let on to raise it to the required temperature.

Before the introduction of wet rolling, flax-straw was steeped for sixty and seventy hours. This improvement, with judicious management, has reduced the time to forty.

When fermentation has proceeded far enough, the vats are emptied, and the straw is immediately rolled. Before being caught by the rollers (Fig. 10) jets of pure water from a pipe above the feed table, fall upon it with a cleansing effect.

After passing the first pair, it is taken by a second and a third, between which it may be turned. Much of the epidermis is thus removed, thereby facilitating the subsequent processes of drying and scutching.

A system of levers is applied to each pair of rollers, which may be understood by a reference to Fig. 11.

Fig. 11.

The weight A, equals 124 lbs. Its distance from the prop B, is 43 in. and the distance of the power C, from the prop is 3 in., therefore  $\frac{124 \times 43}{3} = 1777$  lbs., the power. Calling this power the weight in the upper lever, its distance from the prop F equals 17 in., and the distance of the power E, from the prop is 9 in., therefore  $\frac{1777}{9} = 3356$  lbs., the pressure on the flax as it passes through each pair of rollers.

All kinds of flax will not bear the same amount of pressure. This however, is easily graduated by moving the weight A, nearer the power C.

As the flax leaves the rollers it may be treated in different ways which are described in order.

The first is field drying, which is by far the best, if sudden changes of weather were not to be encountered. Even with this drawback it must not be overlooked.

Fig. 12.

A woman puts a band round the top of a bundle of Flax after it leaves the rollers; these are laid on a truck, and carried by rail to the field. They are dexterously set on end in a sugar-loaf form (Fig. 12) and known as rickles. In some retteries, the bands are taken off, and the ends opened. When perfectly dry, they are bound and put in stacks.

Fig. 14.

But Flax may be put in holders as it come from the rollers, and dried in sheds in the field, or by hot air in the drying-house.

Holder are made of two pieces of wood of various lengths, on the end of one of which are two rings of wire, which, when drawn

over the ends of the other, hold the Flax evenly spread.

An end view of a drying shed is represented by Fig. 13, in which there are two rows with three tiers in each.

Fig. 14.

The next method of drying is by stove, in what are sometimes termed desiccating houses. These can be at work at all times, thereby enabling the manufacturer to control his own operations. But it has been observed that Flax thus dried is somewhat deteriorated in quality.

Two methods of hot air drying are in use, each of which merits a separate notice.

In Figure 14, A represents fanners which

drive cold air, through a range of pipes (C) only one of which is here shown. The flame from the fire in B passes among these pipes, bringing them to a red heat. The air, in its passage through these, is necessarily warmed, and enters the drying house (D) at a temperature of 140 degrees. Here flax is dried in from eighteen to twenty-four hours. Much fuel is used by this method.

The stove represented by Fig. 15; consists of twenty-one pipes arranged horizontally in three rows of seven each. They are six feet in length,

underneath,, but separated from them by bricks, is a fire of coke. The arrows, Fig. 16, show the course of the flame.

Fig. 15.

In Fig. 15, A shows the ends of the tubes, B the fire, C, the ash-pit, and D, the cold-air flue. The air admitted by this flue circulates among the pipes, is heated there, and escapes through an aperture above them into an iron

chamber on the floor of the drying house, which it now fills.

Drying-houses generally admit three tiers of Flax in height, and six rows in width. Rows of studs are set up, reaching from floor to ceiling.

Fig. 16.

Fig. 17.

18.

Fig. 21,

Fig. 20.

Horizontal bars are nailed to these in a longitudinal direction, on which the holders are suspended. The apartments are air-tight above. The only means of escape for the air as it becomes charged with moisture, being by descent to apertures in the floor leading to shafts, and up these to ventilators in the roof.

All Flax, after drying, improves by stacking. Technically speaking, it *comes*. Temporary sheds answer every purpose, if the roofs are water-tight.

The next operation, in order, is scutching.—The straw, in its passage to the scutching-room, is again weighed, and the loss by steeping and drying ascertained.

Before scutching, it is usual to pass the Flax-straw through a breaking machine. Since the introduction of wet-rolling, and scutching machines, this has been partially discontinued.

The simplest form of break is of a mallet shape, (Fig. 17) and is much used in Belgium.—The Flax is broken by successive blows from its serrated surface.

Another form of hand-break is represented by Fig. 18. which consists mainly of two sparred frames, the upper movable on an axis at B, and the lower fixed. It is so constructed that the bars in the lower frame fit between those of the upper. The operator takes hold of the implement by the left hand at A, and with the right places some flax over the lower frame; the upper frame is then lowered, thereby breaking the woody portion of the stems. The flax is successively brought forward and broken until ready for hand scutching.

Breaking in retteries is better done by machinery than by hand. Fluted rollers of wood or metal are mostly used. One of these is represented by Fig. 19. Four or five pair of these work in a machine, one above another in each pair. The flax is fed from a table, and caught between the first pair, then by the second, third, fourth, and so on in succession.

These rollers are seven inches in diameter.—The teeth of the two first pair project an inch, and are severally one and a quarter, and one inch distant from breaking edge. Those of the three last pair project a little more than half an inch and are three fourths of an inch apart.

The first pair revolves a little slower than the second, the second than the third, and so on. Pressure is given and regulated by weight.

Hand scutching of flax is still a very common practice; but it is tedious and expensive on the whole. The simplest apparatus for the purpose is represented by Figs. 20, and 21. The former is the flat blade or sword, with its balancing point, and the latter is the stock, in a slit in which A, a handful of flax, is held by the left hand of the operator, and struck by the scutcher in his right. New surfaces of the flax are presented to the blade, till all the wood is beaten out, and it is perfectly clean.

After flax is broken it is stricked, that is, made into stricks for the scutchers. A strick is as much flax as one hand can grasp, evenly arranged, and slightly twisted. One girl stricks for two scutchers.

Fig. 22.

In mill scutching several wheels are fixed on a shaft distant from each other three feet or more. It will be seen by Fig. 22, that scutching blades of wood or metal, are screwed to the periphery of these wheels. Upright pieces of metal (B) called stocks, are so placed, that the blades as they revolve pass near their surfaces.—The tops of these stands are sometimes on a level with the shaft, and sometimes higher.—The blades are  $\frac{6}{8}$  inch, and  $\frac{7}{8}$  inch from stock at striking point, and  $\frac{4}{8}$  and  $\frac{5}{8}$  at heel. Wheels are three feet six inches in diameter.

A boy supplies each scutcher with straw, weighs each bundle before delivering it, and enters the quantity against his name. This is a simple form of entry.

| Name. | Straw. | Flax. | Yield per cent. |
|-------|--------|-------|-----------------|
|       |        |       |                 |

Fig. 23.

The quantity of scutched flax done by each workman per day is weighed, the percentage of fibre from the straw calculated, and the comparative merits of the several scutchers ascertained. Scutching-wheels make from two hundred to two hundred and fifty revolutions per minute.—They are covered in to prevent dust and accidents.

It was before noted that scutching machines are now made which do away with skilled labour.

Fig. 24.

A large per centage of codilla, or more commonly, tow, is made in scutching. Different methods are in use to effect the separation of

the shove or woody stem. Tow machines are a substitute for hand-picking. Fig. 24 gives a front view of one of these. The wooden arms A, which project in front, are alternately raised and depressed by cranks on their respective axles, connected by rods with others on the driving shaft below

The alternate striking of the tow by these arms has the effect of separating the shoves which fall through the wires B. These shoves are commonly burned and the ashes used as manure.

Tow, like flax, varies much in quality. There are A 1, A 2, B, C tow, &c. A 1 comes from the sorters', A 2 from the scutchers' bags; B and C are the codilla from the machine.

Fig. 25.

Flax is taken from the scutchers to the sorting-room. Here it is sorted into first, second, and third qualities, each determined by the judgment of the workman. It is commonly

made up in bundles or stones of fourteen pounds each. One method is represented by Fig. 25, in which the sorter lays the stricks lengthwise over three bands, with which the bundle is tied when finished.

Fig. 26.

By another method a twist is given to the strick. It is then doubled at the centre and the two ends brought together as in Fig. 26. A band is then passed round their twisted ends, making them ready for bagging. Two hundred weight are put in each bale, or sixteen stones of fourteen pounds each. The flax is now ready for market.

A store room for flax is no unimportant part of a flax factory. If flax is kept too dry it loses in weight and quality. It should be closely packed together in a dark and damp apartment.

Flax has now been brought to that state in which it is purchased by the spinner. But before saying anything of spinning, a description of Watt's chamber for steaming will serve to complete the routine of flax preparation.

It has been before observed that the only point of difference at the present day between the system of Schenck and that of Watt is, that in the former, fermentation at a high temperature is its main feature, while in the latter, the chief characteristic is maceration without fermentation. To Watt, however, is due the extensive introduction of wet-rolling.

A chamber, of which Fig. 27 is a section, may be described as a hollow, air-tight vessel, made of cast iron plates. It is about twelve feet in

Fig. 27.

length, six feet in width, and six feet in depth, including the space between the false and true bottom, which is about nine inches in depth; but not including the condensing cistern, (A,) on the top of the chamber, which is sixteen inches.

The hot water cistern, (B,) set in the condensing cistern is three feet square. A tube, (C,) in the interior of the chamber and running lengthwise is connected with it, by which the chamber is two thirds filled with liquor immediately before steam is admitted.

In the interior of the chamber we find the steam-pipe between the false and true bottom pierced with holes to allow the escape of steam. Above the steam-pipe is the false bottom (D,) consisting of perforated plates, supported by a frame work on feet; also a bar connecting the two sides of the chamber to prevent their expansion or collapse.

On the outside of the chamber are found an air-valve, for the admission of air when steam is shut off, two cocks to indicate the quantity of water in the chamber; and two doors, one in each end opening outwards, each 2 feet 5 inches square. These are used for filling and emptying, and are screwed up and made steam tight by a gaskin of tow. There is also a pipe for admitting steam to the chamber, exhaust steam from the engine is used,) and another for the escape of the steep liquor. Surplus steam escapes by a safety valve on top.

When flax is ready to be taken out of the chamber, the steep liquor is drawn off into an underground cistern, and there mixed with the overflow from the condensing cistern with a view to its future use in other chambers. The same regard is not had in practice for a condensing surface on top of the chamber as the theory of Watt's system exhibits.

The test by which flax is known to be sufficiently steamed, is the easy separation of the epidermis between the finger and thumb. All subsequent operations in this system, as rolling, drying, scutching &c., resemble those already described, and require no separate notice.

Figure 28 represents a ground plan of a Flax Factory on the system of Schenck. A is the boiler-house; B, the engine room; C, the scutch mill; D, the seeding house; E, the steeping house for the vats; F, the wet-rolling house; both of which are under the same roof; G is the tow-room; H may be used as a store-house; I is a workshop; J and K are drying houses; N is the reservoir which supplies the establishment with water, among other things the tank L, in which water may be heated by steam for the vats; and M is the stove.

Grounds for a stack-yard and drying field are usually attached to a rettery of this description.

Flax passes from the rettery to the store of the spinning-mill, from which it is selected and roughed. The finer qualities are taken to the flax-breaker, where the ends are cut off. These are called cut-line, and are spun to low numbers

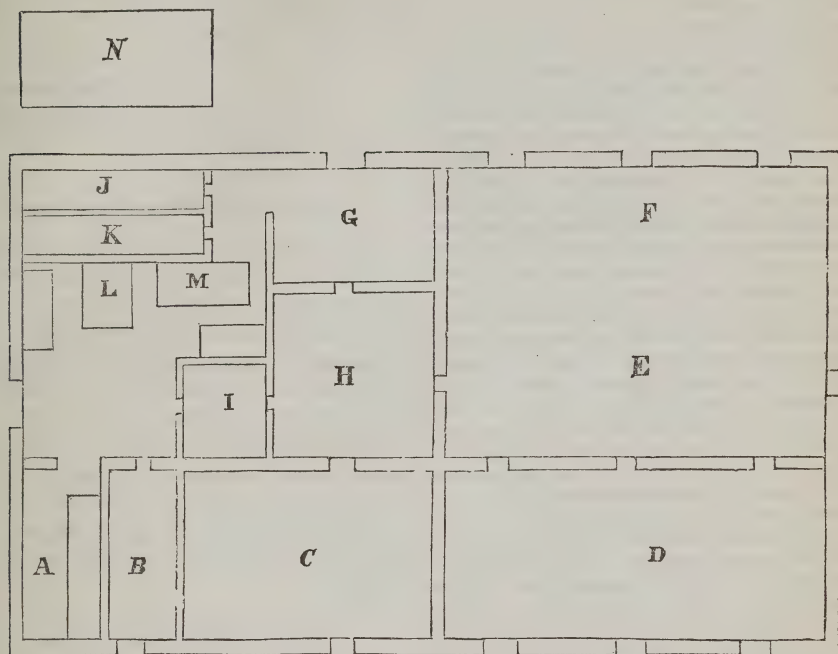

The remainder is called long-middles. The object of cutting is to remove all scabs and impurities which generally exist in the ends of Flax.

After cutting, it is hackled by machinery and taken to the sorting department, where it is selected for different numbers, either for warps or

wefts according to the judgment of the operator.

The tow from the hackling machines is carded and spun to 40 s. and 50 s., for coarse fabrics, as towels, sheetings, &c. It is called first, second and third machine tow.

[Scale 40 feet to the inch.]

Fig. 28.

Flax, after dressing, is taken to the spread board, where the cut-line is spread in four slivers. These are seized in the retaining rollers, and afterwards caught on the reach by the gill. The reach is the distance from the retaining to the delivering roller. This varies according to the quality of Flax worked. The delivering roller makes from twenty to thirty revolutions for one of the retaining, thereby drawing the sliver twenty or thirty times.

Four slivers are united into one, and receiving in a can holding a certain quantity, which is announced by the ringing of a bell, when the can is doffed. The cans so doffed are put up for a second drawing behind another frame, pass over the reach as before, are drawn twelve times, and twelve slivers united into one or two. We have now  $12 \times 20 = 240$ .

These slivers are taken to the third drawing frame, where the same process is repeated, that is, again drawn out twelve times, therefore  $12 \times 240 = 2880$ , which is the number of times the original sliver has been extended.

The cans are now set behind the roving frame,

where the sliver passes over the reach, and is delivered on a bobbin, receiving a twist from the flyer.

Bobbins from the roving frame are taken to the spinning frame. Here they pass through troughs in which water is heated from 100 degrees to 150 degrees by steam, thence to fluted rollers, the reach of which is longer or shorter as the sort spun is finer or coarser.

Finer numbers receive more twists than coarser.

Yarns pass from the spinning to the reeling room. Reels are 90 inches in circumference; each contains 20 hanks, each hank 12 cuts, and each cut 300 yards.

These yarns are taken to the drying loft, and subjected to a high temperature, and when dried made up into bunches for market. Here I will leave them, merely remarking that they are now ready to appear as a textile fabric; assuming the appearance of ordinary linen, or a damask table cloth. In either case before showing themselves in the warehouse of the merchant, they must undergo the operation of bleaching, which itself supports large manufactories.

### Flax Culture.

In a late number of the *Toronto Globe*, we find another letter from Mr. Donaldson on this subject, which contains some additional information to that embodied in former letters. Mr. Donaldson says :—

Canada should turn her attention at once to this subject, and embrace the opportunity of growing every acre the farmer can put in, as it is in contemplation, with several capitalists here, to put up machinery in Canada, the moment there is sufficient flax grown in the country to warrant them in this undertaking. Now that the Spring is at hand, and the Scutching Mills are already on your shores, ordered by the Canadian Government, parties wishing to try them should make application, without loss of time, to the head of the Bureau of Agriculture, Quebec—the machines having no doubt, reached Toronto before this. The cost of cultivation should not deter the Canadian farmer from making the trial of a few acres, as there is not an acre of flax raised in Ireland that does not cost from six to seven pounds sterling—including seed, rent, taxes and labour—before it is ready for our market, and farmers this season, where they have been at all fortunate in getting a fair crop, realized from £80 to £90 a ton, and many of them a great deal more. The quantity of seed sown to the acre should not be less than 2 bush. of 56 lbs., as it is an advantage to have it thick enough to have the fibre evenly and of the same grist. If farmers are not convenient to a mill, they can put the straw in the barns, sheds, or stack it up, after it has been grassed, and the longer it is kept in this state the better the fibre becomes. It is highly recommendable to farmers in the western part of the Province, where more flax growers are than any other place, to endeavour to pull a portion of it before the seed is ripe, as in this state most of the flax that brings the best prices is harvested. The ground should be in good tilth, after having it well ploughed and harrowed, and above all things clear of weeds, then it should be rolled, then the seed sown, then harrowed with a light seed harrow, again, and lastly rolled. Often farmers here sow their clover and grass with flax, as they find in pulling, the flax helps to mould the young clover plant, and seldom, if ever, you will see patches missed, which is often the case with either barley or oats. Farmers in the country who have not much experience in the culture of flax, should go to Norval, Township of Esquesing, or to Canestoga, county of Waterloo, and they will see for themselves the process carried on, both in the cultivation and preparation for the market, by the milling and manufacturing carried on at both these places; and in the place of being able to realize \$15 to \$16 an acre in

growing fall wheat, and less at the present prices of other spring grains, they will get from \$30 to \$40 clear out of flax, and twice that when they come to understand the steeping and handling thoroughly, as they do in Germany, Belgium, Switzerland, or any flax growing country.

Hoping to hear of a flax association being formed immediately in Canada.

I am, dear Sir,

Your obedient servant,

J. A. DONALDSON,

Canadian Government Emigration Agent.

Belfast, March 6, 1852.

### The Flax Scutching Machines.

The Flax Scutching machines imported by order of the Canadian Government, from Ireland, of which a cut and description are given at page 99 of this volume, have arrived, and are at the date of writing, at Toronto. Of the six machines imported, three are to be placed in Lower Canada, and three in Upper Canada. Of these, one is presented to the Board of Agriculture in each section of the Province; to be used under their direction and control. Of the two remaining mills for Upper Canada, one is for the present to be placed at London, and one at Kingston.

### The Composition &c. of Milk.

[We have much pleasure in presenting to our readers the subjoined lecture on Milk, delivered by Professor Voelcker, the Chemist to the Royal Agricultural Society of England, at a weekly meeting of the council, held in March 12th.—Eds.]

#### COMPOSITION OF MILK GENERALLY.

Milk is essentially an emulsion of fatty particles in solution of *caseine*, or curd, and milk-sugar. The fatty matter of milk, however, is not contained in it in a free condition, but enclosed in a little cell, consisting of the very identical substance which, in a state of solution, exists in milk, and which is participated when milk gets sour. In other words the butter, or the fatty portion of the milk, is encased in curd. I have here some milk globules, and they are of different sizes in different species of animals, and even in animals of the same kind they vary from the 1-2000th to the 1-4000th part of an inch. They are generally round, but sometimes are slightly egg-shaped. The yellow spots represent some of the epithelium cells which are generally found in minute quantities even in sound

milk. In addition to the substances just mentioned, milk invariably contains a certain portion of mineral water, and it is important to notice that this mineral matter consists essentially of the same materials of which the incombustible part of bone is composed. The ash of milk is rich in phosphate of lime and phosphate of magnesia, or bone earth. Butter, curd, milk-sugar, and mineral substances are the normal constituents of milk. In diseased milk, we find a number of accidental matters which cannot be identified by any chemical test, but may be well identified by means of the microscope. In diseased milk, pus, or common matter, generally manifests itself under the microscope, but even the microscope is not sufficient in all cases to prove whether the milk is wholesome or not, or whether it is conducive to the health of animals or the reverse. In many instances the constituents of food, or any substances which have a decidedly medicinal effect; pass rapidly into the milk, and confer the medicinal, properties upon the milk which the remedies themselves possess. Thus, if an animal takes castor oil in considerable quantities, the purgative effects of the oil pass into the milk. Colouring matter, the red colour of madder, and the blue colour in indigo, the common weed *mercurialis annua* and *polygonum aviculare*, likewise pass into the milk and colour it. There are also, no doubt, smelling substances which rapidly pass into and give a peculiar taste and flavour to the milk, and when these peculiar flavouring substances are largely infused they affect the milk. Thus we know that the turnip flavour, for example, is readily imparted to the milk. Milk appears white on account of the suspended milk globules. In the measure in which those globules separate in the shape of cream, and milk becomes clearer, and acquires a peculiar blueish tint, which is a very good indication of the character of the milk. The less transparent it is the better; the more opaque it is the more butter it contains. And allow me here to notice that the quality of the milk is much more regulated by the amount of butter than of cheesy matter. An extensive series of analyses which I have made of milk have brought out this fact, that whilst the proportion of *caseine* varies but in a trifling degree, the amount of butter or fatty matter in milk is subject to very great varieties indeed. If you throw a glance at the tables on the wall, you can form an idea for yourselves of the great variations that exist in the amount of butter which a given quantity of milk is capable of yielding. Thus, in the first sample of milk you have no less than  $7\frac{1}{2}$  per cent of butter, in the second 5 per cent, in the third  $3\frac{1}{2}$  per cent., and in the fourth only 2 per cent. I have separated these analyses from a number which I made some time ago, and I have further increased them by analysing, from month to month, during the past season, the morning and evening

milk of our dairy cows, and greater variations than those given here I have not found. These four examples, therefore, may be safely taken as indicating the wide range of the variations which exist between the different constituents of milk; the specimen of milk which is exceedingly rich in butter is derived from a sample from the dairy of Mr. Harrison, at Foster Court. The second sample indicates a richer butter than usual. The third fairly represents the composition of milk of average good quality. And the fourth that of milk of a poor quality. But they are all four genuine milks. They are not in any way reduced abnormally; and I ascribe the great richness of the first sample to the extreme good pasture upon which the cows had been fed, at a season of the year when generally, milk becomes richer in quality, but less in quantity. In the months of September and October, and up to November, the quality of the milk very greatly improves, but the quantity recedes and becomes smaller. Whilst, however, this is true generally, it is not so always; for if the animals are stinted in food, they yield not only little milk, but also a poorer milk, and that at a period of the year when they should, and generally do, produce a richer milk. Speaking generally, milk is richer in the fall, and poorer in the spring of the year. But other circumstances may influence the character of the milk so as to produce different results. I shall have to speak presently more in detail of the various circumstances by which the quality of the milk is modified; but before doing so, I will point out the great difference in the composition of the milk of different animals.

#### COMPOSITION OF MILK OF DIFFERENT ANIMALS.

And first let me direct your attention to the composition of the milk of herbivorous animals—the cow, the ass, the goat, the ewe; and then the milk of carnivorous animals—the canine race, taken as an example of the suspension of milk. You will notice that the milk of carnivorous animals is very much richer in all its various constituents, more especially in *caseine*, or curd, and also in butter. It is an extremely rich milk and we have no food to compare with it. Solid butcher's meat contains less real food and more water than this description of milk. This will explain at once the extreme difficulty we experience in bringing up a puppy dog by hand. The fact is, that you have no food rich enough for that purpose. Perhaps the only food available, if you had to rear a valuable puppy by hand, would be a highly concentrated beef tea; that is an infusion of beef highly concentrated. No solid food or pure flesh is sufficiently concentrated to provide for the nourishment of a young dog. It is not only the amount of curd, but also the amount of butter, which is extremely rich. There is another peculiarity also. It is this: that the milk of carnivorous animals contains no milk-sugar at all. Milk-sugar, however, is very abundant in the milk of other than carniv

vorous animals; and curiously enough, it makes its appearance in the milk even of carnivorous animals when, by domestication, they are gradually accustomed to a bread diet. If you feed a dog with bread, the milk increases, and will contain some milk-sugar, and that quantity increases with the amount of bread and the starchy food with which you supply the dog. This shows the intimate connection which subsists between the character of the food and the composition of the milk of animals. Contrasted with the milk of carnivorous animals, the milk of the ass appears most inferior, and an extremely poor milk. But whilst it contains, as indicated in the analysis, 91½ per cent. of water, little *caseine*, scarcely any butter, and a very small quantity of ash, it is comparatively speaking rich in milk-sugar. Now, milk-sugar is a very digestible material. It is easily digested. Indeed, on the continent it is used as medicine in cases of indigestion. It is a household medicine for children. Children suffering from indigestion have administered to them a teaspoonful or two of this milk-sugar or *lactine*, as it is also called; and as an aperient medicine, I do not know another so wholesome. For invalids, therefore, ass's milk is, no doubt used in this respect—that it is an easily digested food. Persons suffering from indigestion are frequently unable to well assimilate the butter which is contained in good rich milk, and ass's milk, for this reason, is peculiarly well adapted to them. I question much, however, whether the composition of the milk of all donkeys is so poor as this. I ought to mention that my analysis is made of the milk of a German donkey, which, like Irish donkeys, is fed on the road side, not upon the richest of food. In short, it eats what it can pick up; but I believe that a well-fed donkey would furnish a much richer milk. I am led to this belief from having seen, by investigations, which I hope to publish in future number of the Royal Agricultural Society's Journal, on the variations in the composition of milk, what an important influence the amount and quality of food have upon the composition of milk. For a moment or two, allow me now to point out a few particulars with respect to the milk of ewes. I have here the composition of two samples of ewe's milk. Both were analysed by myself recently; one a fortnight ago, and the other was completed only the day before yesterday. The first sample of ewe's milk I had the pleasure of analysing for his Grace the Duke of Richmond, who had experienced a great many losses in his flock of sheep. Many lambs had died, and his grace thought it probable that the milk of the ewes was of a poor character, or contained something that was injurious. I put it under the microscope, and subjected it to a careful examination; but I found it perfectly normal. No pus, or other matter, which occasionally occurs in diseased milk, was present; and on comparing the analysis with the published analyses of ewe's

milk, I found it agreeing as nearly as you could expect in two samples of milk. The published analyses of ewe's milk made it closely resemble goat's milk, for this reason; but on analysing the milk from our own ewe pen I was struck with the very great difference in the quality. You will observe that in the first sample of milk, which is from the ewe pen of the College Farm, we have no less than 30 per cent., in round numbers, of solid matter; whereas, in the second sample we have only 16 per cent. There is thus, in the one sample of milk, nearly double the quantity of solid food that is in the other. I have not learned what time had elapsed from the ewes having lambed; but the milk analysed by me from our own ewe pen is derived from ewes that had lambed only three days previously. Now, the time at which the lambs had dropped has unquestionably great influence upon the quality of the milk. We know that the very first milk which is yielded by the ewe after the lamb is dropped is more like cream than butter. The sample I have before me is not the very first milk: it is milk that was secreted two or three days after. I gathered it from a number of ewes, and all had lambed within that period; but I was not prepared to find so great a variation. It is an important subject to ascertain what are the variations in the milk of the ewe at different times. But we have no data for making that comparison; and although I have made a report to his Grace the Duke of Richmond, that the milk of the ewes was of good quality when compared with other samples of ewe's milk—analyses, however, which were not made in England, but on the Continent—it is very possible that a poorer milk is produced, and after all that this milk was of an inferior character and of poorer condition. At any rate it is interesting to notice the high state of concentration of the milk that is yielded by ewes in the first week, or even three days after lambing. It is an extremely difficult thing to bring up a lamb when its mother dies within the first three or four days. There is a peculiarity in the condition of ewe's milk which throws some light upon the subject, and it shows the reason why such difficulties are experienced. I propose now to reserve a couple of ewes, and analyse their milk from time to time, in order to see if the milk gradually becomes poorer, or remains stationary, and also with a view of ascertaining what the average composition of ewe's milk is.

#### CIRCUMSTANCES AFFECTING THE QUALITY OF MILK.

Passing on, I would notice some of the circumstances by which the quality of milk is affected. The distance from the time of calving I have already referred to; I may, therefore, pass it over here, and refer briefly to the age of the animal. It is well known that an old cow does not yield such good milk, nor so much milk. I have lately seen an analysis of milk which gave

quite as poor a result as the one I have mentioned; it is that of milk analysed in Holland by Dr. Baumhauer. He states that it is the milk of a cow that had had ten calves, and nothing appears to be so unprofitable as to keep cows for so long a period. Generally speaking, as is well known to practical men, the milk becomes richer after the third or fourth calf has been dropped. The climate and the season of the year affect the quality of milk in a remarkable degree. In the moist and temperate climates we obtain a larger quantity, though usually a poorer description of milk, than in dry and warm countries. The quality of the milk is thus affected by the temperature of the air, and by the amount of moisture in the atmosphere. It may perhaps, be also due to the amount of moisture which in wet seasons is present in the produce; and that the general state of health and the condition of the animals have a marked influence upon the quality of the milk, need hardly be mentioned. It is so well-known, indeed, that no remark is necessary upon the subject. The time at which the milk is taken, however, has an effect upon the quality of the milk. In most agricultural treatises you will find it stated that the morning milk is generally richer than the evening milk; but my results do not favour this notion. I find the following to be the case;—Out of 32 samples of milk which I analysed, taking the morning and evening milk, I found that of 16 different cases, in 8 the morning milk was poorer than the evening milk, in 4 the morning milk was richer than the evening milk; and in the remaining 4 there was no perceptible difference between the quality of the morning and of the evening milk. I mention this particularly, in order to show how careful one should be not to generalise, to come to a conclusion hastily. At first I took it for granted that the morning milk was richer; and, indeed, the first three analyses I made confirmed that general impression. I need not go over the results at present. I merely mention the general effect. The first three mornings' milk which I analysed were, indeed, richer in milk; but on extending the series of analyses, I found afterwards a larger number of instances in which the evening milk was richer than the morning; and at various times I found that both were perfectly alike. What then, is the general conclusion we should draw from such facts? I believe that the time of the day had not so much to do with it as the quantity and quality of the food which is given some three or four hours before milking. I have traced this most distinctly. At one time I found the milk of our dairy stock was poor in the evening. The cows were then out on grass. They received in the evening, therefore, oil-cake and rape-cake, and then in the morning they produced a richer milk; which shows plainly the effects of the food on the morning milk. And at another time—in the winter—I found that when the

cows were fed in the morning, and again in the middle of the day, with barley-meal and rape cake, they produced a richer evening milk. I believe, then that the quality of the milk is affected by the food, and the time at which the food is given to the cows, and that we certainly cannot say that, in a general way, the morning milk is richer than the evening milk, or that it is poorer. It may be one or the other. It may be perfectly alike, or poorer or richer, as the case may be. The race, breed, and size, of the animal have also an important influence on the quality of the milk; and that Alderneys, Chateaux, and others are noted for the rich quality of their milk is too well known to the practical men to need any comment from me.

Lord Feversham—Have you ascertained what is the difference in the *quantity* as well as quality of the morning and evening milk?

D. Voelcker—The yield was not much greater in the morning than the evening; but I was about to make an observation on that very subject. It is generally believed that the thoroughbred cows do not produce so much or so rich a quality of milk, and that the common dairy stock or cross-breeds produce more or a better description of milk; but some experiments which I have made on the subject have given me a rather undecided result—a result from which I cannot draw any satisfactory inferences. In the month of September, 1860, I selected three cows from the common dairy stock, and three pedigree short-horns. They were kept in the neighbourhood of Bristol, on the present Mr. Stratton's farm, then in the occupation of Mr. Procter. They were on good pasture land, and I carefully ascertained the quantity of milk, and also the quality of the milk. After I had kept them some time on pasture, the milk was collected. I then gave to each set of cows 1 lb. of excellent linseed cake, and in one week's time increased the quantity to 2 lb. I then carefully analysed the milk of the common and of the pedigree cows; but upon looking over the results I could find no perceptible difference between the quality of the milk of the common stock and that of the thoroughbred short-horns. Thus, the common cows yield a milk which returned nearly 4 per cent. of butter, and the thoroughbred short-horns gave within two-tenths per cent. of the same quantity. The total amount of solid matter in each case was just alike. When 1 lb. of linseed cake was given them the quality of the milk was not materially improved. In both cases milk of about the same quality was produced; and the same general remark may be made with respect to the 2 lb. of linseed cake which were given to the cows. In all these cases the quality of the milk was not improved, neither of the common cows nor of the pedigree cows. The quantity of milk produced by the three pedigree cows, kept on

grass alone, amounted to 28 pints in the morning, and 21 pints in the evening, making together 49 pints. The common dairy stock produced rather more, being 31 pints of morning milk, and 21 pints of evening milk, in the whole 52 pints. When they received 1 lb. of cake the three pedigree cows gave in the morning  $26\frac{1}{2}$  pints, and in the evening 22 pints, together 48 $\frac{1}{2}$  pints: very nearly the same quantity as before, (A member—do you mean the three?) Yes; and the three common dairy cows produced 28 $\frac{1}{2}$  pints in the morning, and 18 pints in the evening, making 46 $\frac{1}{2}$  together. When 2 lb. of cake were given to them, the three pedigree cows yielded 26 $\frac{1}{2}$  pints in the morning, and 21 in the evening, together 47 $\frac{1}{2}$  pints; whilst the three common dairy cows produced 30 pints in the morning, and 19 in the evening, to ether 49 pints. It follows from this that, whilst the quality of the milk was not materially bettered, the quantity became slightly less in the case of the three ordinary cows; because we had from the three pedigree cows 49 pints of milk when kept on grass, 48 $\frac{1}{2}$  pints when they got 1 lb. of cake, and the quantity was further reduced to 47 $\frac{1}{2}$  pints with 2lbs. of cake; and from the three common dairy cows, when fed on grass alone, we got 52 pints, with 1 lb. of cake 46 $\frac{1}{2}$  pints, and with 2 lb. of cake 49 pints. It would appear from these facts, then, that the additional food had a tendency to go to meat, or to produce fat. This would show that we cannot increase *ad infinitum* either the quantity or the quality of the milk. Cows that have a tendency to fatten, when supplied with additional food rich in oil and in flesh forming matters like linseed cake, have the power of converting that food into fat. They do not produce a smaller quantity. It is this, then, which renders all investigations respecting the influence of food on the quantity and quality of milk so extremely difficult. Accordingly to theory, it would appear that food rich in oily or fatty matter would be extremely useful for producing a rich milk; but in practice we do not always find this to be so. Indeed we often find that very rich food has just the other effect. It produces by no means a better milk, but a smaller quantity, and fat and flesh instead of milk. Well, I repeat, these things render all investigations on the influence of food extremely perplexing. There are so many circumstances which have altogether a disturbing influence on the food in its passage through the animal system that it is difficult to trace its course, and still more difficult to predict beforehand what will come of it.

#### INFLUENCE OF FOOD ON MILK.

These remarks lead me naturally to speak a little more in detail of the influence of food on the quality of the milk. I just now noticed that the quality of the food, the composition of

the food, does not always indicate its adaptation or fitness for producing a good and an abundant quantity of milk. For, besides the tendency which cows that are good fatteners have to convert peculiarly rich food into fat, there are some purely practical considerations to be taken into account before we can decide upon the quality of the food which ought to be given to milking cows. It is well known that oily matters pass rapidly into the milk. Cows that are supplied too abundantly with linseed cake produce milk that does not make butter. A very curious instance was brought under my notice some time ago, by Mr. Barthropp, of Crettingham, in East Suffolk, of milk furnishing cream that could not be made into butter. When put into the churn it beat up into froth, and could not be converted into butter; the *caseine* would not separate, and I have been informed by Mr. Barthropp that he had given his cows linseed-cake in considerable quantities. This excess of linseed-cake, and, perhaps, the want of good dry hay, have evidently the effect of producing too much liquid fat; and in trying to separate as well as I could the solid or crystallised fat from the liquid fat I obtained this proportion: one-third of solid fat, in round numbers, and 23 parts of liquid fat. In churning the whole of it was made up into a sort of froth; in fact, it could not be churned. The butter remained a liquid, even at the cold period of the year when the milk was analysed—namely, last January. I have never become acquainted with so striking a case, as showing the influence of a great excess of oily food on the quality of the cream and butter. In speaking of the quality of cream, more especially the fatty portion of it, the butter, I would likewise take this opportunity of observing that bad oil-cake, and especially bad linseed cake, does a great deal more harm than is generally supposed by the dairymen. The inferior taste of the milk of stall-fed cows is well known; but I believe it is not so well known that the wholesomeness of milk is affected by the abominable matters which are occasionally put into linseed cakes. At the present time, oil-cake crushers seem to enjoy the privilege of incorporating any kind of oil refuse, no matter what it is, with linseed cake; and since this has been so, we hear more frequently of diseased milk, and of milk which has a disagreeable flavour. When the necessity arises for feeding cows with additional food, and linseed cake is found by practical men to be preferable to other kinds of food, I would suggest that it is money well laid out to buy the very best and finest cake, and not, for the sake of the lower figure, get it of an inferior quality. The use of water-food, distillery wash, the acid waters of starch makers, and similar refuse, make the milk, as is well known, watery, and dispense with the necessity of mixing water with the milk afterwards. By far the most commonly adulterated material

is watery food. Water is not so much added to the milk, after it is drawn off from the animal, as it is incorporated with the milk in the system before. It is well known that food which contains lactic acid has a tendency to produce an abundance of milk; and when animals are fed with concentrated food, such as bean-meal or cake, it may perhaps be advisable, in the absence of brewer's grains or distillery refuse—two materials which contain lactic acid—to generate some lactic acid by keeping barley meal for some time in contact with water, and letting it slightly ferment, perhaps with some vegetable refuse matter, which has a tendency to hasten the formation of lactic acid from barley meal. By doing this, I am inclined to think that concentrated food, like cotton cake, bean-meal, or rape-cake, would be rendered more digestible, and more readily made available for the production of milk of a good character. Time does not permit me to speak in detail of the influence of the various kinds of food upon the quality of the milk; and I purposely cut it short, in order that, if some spare time is left, those who are practically better acquainted with the subject than I am may have an opportunity of throwing out some hints, and perhaps of opening up a little discussion respecting it. What time I have at my disposal I hope to fill up usefully by directing your attention to the mode of testing the quality of milk.

*(To be concluded in our next)*

### On Steam Cultivation—its rise and Progress.

A very interesting paper on this subject was read at a recent meeting of the London Farmers' Club, in England, by Mr. James Howard, the celebrated Implement Maker, of Bedford. The following paragraphs give the substance of the communication, which will not be devoid of interest to our readers generally.—Eds.

*Influence of Steam Power.*—It may appear startling, but 'tis no less true, that to the discovery of the steam engine, more than to any other cause, this country owes its great wealth, its manufacturing greatness, and the means of supporting its abundant population.

"Until the discovery of this mighty agent, the population and the wealth of England were almost at a stand still. So lately as 1780 we only numbered 8 millions; and 200 years before the population was 6½ millions. No sooner however, was the steam engine fairly brought into use than that wonderful expansion of our commerce commenced, which brought with it a corresponding increase in population, and which has made England the great mart of the world. The quick processes, and rapid results of the fac-

tory have of late years been imported into the thrashing of our crops; no wonder, then, that the farmer has begun to regard the ploughing of his land by-horse-power as a slow and tedious operation, and has become desirous of introducing into his fields the same despatch and the same powerful agency he has found of so much advantage in the preparation of his grain for market."

*History*—Although, until a recent period, public attention had hardly been turned to the question, steam ploughing is by no means a new subject.

"(1) As long ago as 1618, one David Ramsey and a Thomas Wildgoose obtained a patent for 'Newe, apte, or compendious formes or kinds of engines or instruments, and other p'fitable invencons, wayes, and meanes, for the good of our Commonwealth, as well as to ploughe grounde without horses or oxen, and to enrich and make better and more fertile, as well barren peate, salte, and sea sande, as inland and uplande grounde, within our Kingdomes of England and Ireland, and our Domynyon of Wales; as alsoe \* \* \* to make boates for the carriage of burthens and passengers runn vpon the water as swifte in calmes, and more seff in storms, then boates full sayled in great wynds

"(2) In the same year that Ramsey took out his last patent, a William Parham and others had a patent granted for a 'certain newe and readie waye for the good of our Commonwealth, for the earinge and plowing of lands of what kind soever, without the vse or helpe of horses or oxen, by meanees of an engine, by them newly invented and framed.'

"(3) About 40 years after Ramsey and Wildgoose, another genius arose, named Francis Moore, who took out no less than three patents, having for their object 'the dispensing with animal power in tillage, navigation, &c., &c. Mr. Moore states, 'his machiue to go without horses.' 'Tis recorded in a periodical of the day that Mr. Moore had such faith in his inventions that he not only sold his own horses, but by his advice many of his friends imitated his example, fearing their value would be affected by the general introduction of his machine.

"(4) About the same time, 1770, another inventor appeared, a Mr. Richard L. Edgeworth, who patented an engine with an 'endless railway,' almost identical with that patented by the late lamented Mr. Boydell.

"(5) In 1810, in which year a Major Pratt obtained letters patent for a steam ploughing apparatus. One of his schemes was to place the engine and anchor on opposite headlands, or in boats, as Mac Rae's. The implement described by Major Pratt may be regarded as the first 'balance plough,' the ploughs being placed back to back, or heel to heel, and working on a fulcrum in the frame, one set being thereby raised out of work while the other set was lowered into work.

"(6) Between 1810 and 1832, numerous schemes were propounded and patents taken out for ploughing, digging, or trenching the land, by eegines working in various ways, but I find nothing of real value until the latter year, when the celebrated John Heathcote, M. P., a lace manufacturer of Tiverton, obtained a patent for certain new and improved methods of draining and cultivating land, and new or improved machinery and apparatus applicable thereto."

"His engine travelled along the headlands, and when ploughing bogs was constructed with an endless web, forming an endless roadway. His anchor, called by him an 'auxiliary carriage,' also moved along the headland as the work proceeded. Mr. Heathcote described in his specification a means of making his anchor self-propelling. The engine he proposed to fit with two winding barrels, one on each side, so as to work either one or two sets of implements at a time."

In connection with Mr. Heathcote's scheme, I may mention one fact highly honourable to the foresight and public spirit of the Highland and Agricultural Society of Scotland.

"As long ago as 1837, this society offered a premium of £500 for the first successful application of steam power to the cultivation of the soil. Mr. Hall Maxwell, the zealous and indefatigable secretary writes me :— 'At the society's show held at Dumfries the same year, £100 in addition was subscribed to pay the expenses of exhibiting and working what was called 'Heathcoats' Plough.' 'The trial of this plough was to some extent satisfactory : but the judges did not consider the implement sufficiently perfect to entitle it to the premium. The society, however, continued to offer the prize until the year 1843."

"Some 20 years afterwards, the Royal Agricultural Society of England followed the example of the Highland Society, by offering a prize of a similar amount, and it would have done well and saved a great deal of 'heart-burning' if it had also followed the Highland Society in the simple wording of the offer, viz., 'the first successful application of steam power to the cultivation of the soil.'"

"(7) Mr. Heathcoat was followed by Alexander Mac Rea, who in 1839 obtained a patent for 'machinery for cultivating land by steam power.' The primary object it would appear, was to adapt his apparatus for use in British Guiana, where the fields are intersected by wide ditches and canals.

"Mac Rea, although his engine and anchor are shown working in boats, described his apparatus as applicable to the unlevel lands by working the engine and anchor along the headlands.

"The implement of this inventor is worthy of notice, for, as the drawings show, it is arranged with the ploughs point to point, as Messrs. Fiskins and Mr. Fowler's, to which it bears a strong resemblance ; Mac Rae also anticipated

our friend Mr. Williams, of Baydon, by having each plough independent of the other, like the coulter of a drill.

"(8) In 1849 Mr. H. Hannam, of Burcote, near Abingdon, a well-known agriculturist, in connection with Messrs. Barrett and Exall, constructed an apparatus for steam ploughing which may be regarded as the first attempt to work ploughs or cultivators by the ordinary portable engine, and also to be the first attempt to plough the land by an engine stationed at one corner or outside the field. We have no evidence that wire ropes were ever employed for steam ploughing until those supplied to Mr. Hannam by Messrs. Barratt and Exall. From Mr. Exall I learn that the ropes were 1600 yards in length, and from the drawings exhibited it will be seen that they were coiled and uncoiled by a stationary windlass, having two winding barrels, in the same manner as those now in use. The ropes were also passed round pulleys at the corners of the fields and now so well known.

"About 60 acres were ploughed or cultivated by this apparatus at the rate of about 5 acres per day, when it appears the rope, from deficient strength, or probably from bad handling, gave way. Doubtless, had more perseverance been shown, the parties would have been rewarded with greater success ; but I very much question whether any system of rope traction would have become a permanent success but for the introduction of ropes made of steel wire, which has contributed very greatly to their durability.

"(9) In 1851, at the great exhibition, Lord Willoughby D'Eresby showed a complete steam ploughing apparatus, consisting of two engines, with a winding barrel on each—i. e., an engine for each headland. These advanced as the work proceeded. A number of ploughs on Lowcock's turnwrest principle were placed in a frame and wound or drawn from engine to engine by a chain. I believe if a wire rope instead of a chain had been employed his lordship would have succeeded.

"(10) Following up the course of invention, we next come to the scheme of Messrs. Fiskin, of Stockton-on-Tees. A stationary engine was employed, a main object of Mr. Fiskin being to dispense with wire ropes, and give off the power of the engine by means of a light, endless, hempen cord, worked at a high velocity, which passed round pulleys on a self-moving anchor, and thence to winding-drums placed upon the implement, the revolution of which imparted motion to the ploughs. The anchors were self-propelling, their onward motion being effected by the revolution of the pulley placed on the anchor and round which the rope was passed ; second, the plough was on the balance principle, and was steered in either direction by means of locking the wheels. This apparatus was exhibited at the Royal Agricultural meeting in 1855, and created quite a sensation ; as well as making a very favourable impression."

(11) In 1854 Mr. Fowler exhibited at the Royal Society's meeting held at Lincoln his steam draining plough and apparatus.

"In the report of this meeting, published in the *Journal*, a diagram is given of this machine. The judges, in speaking of its wonderful performances, wind up with these remarks:— 'Surely this power can be applied to more general purposes; we earnestly commend the idea to our engineers and mechanists.' "

(12) Whether those to whom the idea was commended took much notice of it or not we do not know, but we do know that the idea commended itself to a farmer, in the person of Mr. Smith, of Woolston, who in a published letter informed the public that he commenced his experiments after reading this report.

"Mr. Smith subsequently ordered an apparatus of Mr. Fowler, with which he proposed to work, and subsequently did work his cultivator. An opinion has been prevalent that Mr. Smith has a claim to the invention of the whole apparatus; but in 1856, at a meeting of the Society of Arts, Mr. Smith admitted 'that his first windlass was constructed by Messrs. Ransomes, under the direction of Mr. Fowler.' I do not mention this to detract from the great merit due to Mr. Smith as a pioneer in steam cultivation, but simply that the merit should be properly divided or given to the right party; and I will remark, in passing, that I believe Mr. Smith has done as much or more than any other man in arousing the country to the importance of steam culture, and to the fact that land can be economically worked by steam power; he has also proved that land can be successfully and continuously farmed by simply 'smashing' or stirring, and that inversion of the soil is not so absolutely necessary to successful cultivation as it was generally believed to be."

*Causes of delayed Success.*—Political economists tell us that the "machinery of a country will naturally correspond with its wants, and with the history and state of its people." This is undoubtedly true; the schemes we have described having been invented before they were really wanted or before their need was felt.

"There can be no doubt that a redundant population and the paralysing effect of the old poor law had considerable influence in retarding the use of machinery in farming; also the wide spread and deeply seated conviction that the employment of mechanical power diminished the demand for hand labour; and this conviction, which was shared by all classes, led people to take very little interest in labour-saving inventions.

"Again for want of railways, coal was at such a price, and so distant from the farm, that in most districts half the horse power that would have been saved by the introduction of steam power would have been employed in hauling coal for the use of the engine.

"The revolution which has taken place in

farm practice by the substitution of the steam thrashing machine for the flail and the horse gear has, doubtless, been brought about very much through the intersection of the country by railways.

"This again has led the farmer to appreciate the value of and imbibe a taste for steam-driven machinery; it has, moreover, accustomed him to expend comparatively large sums of money in the purchase of machinery. We are creatures of habit, and 'tis astonishing, when we begin to spend money on machinery or anything else, how easy it is to jump from £300 to £500, and from £500 to £800.

*Classification of Inventions.*—I divide the inventions, which since 1855 have been brought before the public, into the following classes:— 1. Engines to travel over the surface, drawing their implements with them. 2. Locomotive engines working on railways and drawing implements after them. 3. Engines moving along the headlands and working implements by means of wire ropes. 4. Engines stationary whilst at work, and working implements by means of wire ropes. A number of schemes under each head have been either brought before the public or patented; and without using names more than absolutely necessary, I will simply allude to the alleged advantages and disadvantages of each system.

"I would here take the opportunity of stating that in endeavouring to bring steam cultivation into practice, I believe no one has worked harder or spent his money more freely than Mr. John Fowler, and so far as I am concerned I hope he may be amply repaid for his great efforts.

"(1) Engines which move over the land. Under these disadvantages, their weight is immense, and they have to propel themselves over surfaces more or less uneven or more or less yielding; the consumption of fuel and water is at least fourfold that of a stationary engine, and the repairs, owing to the irregularities of the surface of the land and greater friction, would probably be tenfold. The weight of such a machine, passing over the land, is also most objectionable. Mr. Romaine, to whom much praise is due, has worked hard to carry out the principle of a rotary cultivator moving over the surface—a scheme so ably advocated by Mr. Wren Hoskyns. I believe, however, Mr. Romaine has abandoned the plan in favour of rope traction, for which he has obtained one or two patents.

"(2) As to the scheme of laying down rails all over a farm and working locomotive engines upon them, whatever may be the economy and despatch of such a system when once carried out, I think it highly improbable, considering the outlay to be £20 to £30 per acre, that it will ever come into use in this country; at all events, not until landlords generally are much richer, and until a disposition to spend their

money in the improvement of their estates has obtained more hold throughout the country.

"(3) Next in order are the engines which travel along the headlands as the work proceeds. These doubtless employ their power more direct, and with a smaller quantity of rope than engines stationary at one point, but they have these drawbacks: when the soil is at all wet the passing of a heavy engine along the headlands, and the necessary coal and water haulage after it, destroy in great measure the fertility of the headland, as well as leaving a good deal of hard work subsequently to be done by horse power in bringing the land to a tilth.

"Again, in hilly countries the engine is at work sometimes on a steep ascent and sometimes on as steep a descent, at times inclining to the right, and at others to the left; this will doubtless render the cost of keeping the engine in repair much greater than one that is stationary and always working upon the level. Another disadvantageous feature is that a headland all round must be left unbroken if the field has to be worked a second time by steam.

"(4) Lastly, we will take the engines stationary while at work. The main objections urged against these schemes are, the extra length of rope required, and the loss of power by the employment of pulleys round which the ropes are passed; the advantages claimed are, they are less costly to purchase and to keep in repair, more simple of construction, consequently better adapted for ordinary farm labourers, and irregular shaped fields can be ploughed as well and almost as quickly as square ones. By stationing an engine at one point, fields of 30 or even 50 acres each can be cultivated without any remove of engine or apparatus, and if the farm be well laid out, twice this quantity can be done from one point. A pond or a well sunk at convenient spots saves all water carting, and the coal is all brought to one point instead of having to be carted after the engine.

"Some parties have greatly exaggerated the loss of power entailed by the passing of ropes round pulleys. I have heard it stated in this room that for every pulley used a horse power is sacrificed. Now, so far from this being the case, I find by most careful experiments that when working a cultivator drawing 15 cwt., and the ropes arranged in a square, the loss of power from friction is 25 lbs. per pulley, just one-sixth of a horse-power. Even this is not so great a disadvantage as at first sight would appear, for if the pulleys were reduced to two and the same strain put upon them, the friction would be increased one-third; this arises from the fact that the ropes would then have to pass half round the pulley instead of one-fourth only. The experiments at the Leeds meeting proved most conclusively that very little power was lost in the friction of the wire ropes, when properly supported upon pulleys.

"Mr. Pike, in my neighborhood, has a field of 50 acres, in which he stations an 8-horse engine, at the extreme corner, where he has dug a pond. This 8-horse engine, without ever moving, breaks up this field of heavy tenacious soil to a depth of 7 or 8 inches, at the rate of 7 or 8 acres per day: so much for loss of power from pulleys and extra length of ropes."

*Achievements.*—Having now very imperfectly sketched the rise and progress of steam cultivation, I will, in a few words, sum up what I consider what has already been achieved.

"Some 400 or 500 farmers have purchased steam cultivating apparatus, of one kind or other. From the Britannia Iron Works, Bedford, alone, about 200 steam cultivators have been sent out.

"The experience and the opinions of a large majority of the purchasers have been published, and all, or nearly all, have testified to their approval and appreciation of steam cultivation."

*As to the future of steam tillage* I shall say but little. What effect the general adoption of steam power on our farms will have upon the country no one can foresee. To expect that steam will do as much for agriculture as it has done for manufactures and commerce would be idle; but that it will enormously increase the productiveness of the country no one who has paid the least attention to the subject can for a moment doubt. Whether it will increase correspondingly the profits of the farmer we must wait to see; but it is worthy of remark that the most highly remunerative amongst the manufacturing trades of this country have been those which require a large plant in the shape of steam-driven machinery. To the landlords of the country the question of steam ploughing is of the greatest importance, and a few noblemen and landed proprietors have come forward and introduced steam cultivators on their estates; but it is mainly to the enterprise of the tenant farmers that the system has made so much way in the country. Landlords will consult their own interests as well as that of their tenants by removing all hindrances to the adoption of steam power. All unnecessary fences, to say nothing of trees in ploughed fields, must be got rid of; the farms must be properly laid out; and, above all, greater liberty of action must be given to the tenant in the course of cropping and other matters, before the resources of our farms will be fully developed. That the new order of things will have a considerable influence on the labourer I have no doubt. The great advances which have been made of late in agriculture, and the changes which are taking place, force on our notice the fact that a more intelligent and a more careful class of labourers are becoming indispensable to the farmer; and by employing these in the use of a higher order of machinery they will be a field for the more intelligent and useful farm servant. Under the old order of things—however willing to encour-

age the skilful the farmer might be—this was difficult to be found. In conclusion, nothing indicates more clearly the great advance which is being made in the agriculture of this country than the introduction and spread of a better class of farm machinery. The machinery of a country has ever been a gauge of the intelligence of its inhabitants; iron clad ships and rifled guns are not the implements of warfare of barbarous or semi-barbarous nations; nor are steam-driven thrashing machines and steam ploughs the implement of a backward and bigoted agriculture.

### Rot in Sheep.

"Plenty of skins, but we are saying as little as possible about it," was the report recently given us by a friend who lives in a certain sheep-rearing district, which shall be nameless, and of whom we had inquired how matters were progressing with respect to what some call "the woolly people."

"Plenty of skins," is a very significant expression, telling not only of actual losses, but of other points to which we may allude before closing these remarks. And when we see the bleached-like pastures, saturated with water, and the equally bleached-like sheep, with their wool apparently stuck close down upon their skins, but ready to peel off at the slightest touch; when we notice the yellow tinge which pervades the eyes, &c.; the general absence of that sprightliness which characterizes sheep in high health; and when these and other well-known symptoms are furthermore accompanied by the tell-tale "*poke*" then we feel assured that if there is not already, there soon will be "plenty of skins," although the abundant supply of that article is not accompanied, in that case, with either profit or satisfaction to the stockmaster.

But is justly dreaded by the sheep-owner as the most direful calamity which can befall his flock. It sweeps off the animals like a pestilence, and if it is known to exist or occur in a flock, a grave suspicion arises as to the general health of that flock—such a suspicion, moreover, becoming, when made public, a very serious matter; for all who are aware of the stigma will avoid the risk of purchasing when the seeds of a fatal disease may be lurking in the constitution of the animals. For these reasons it is of the utmost consequence to the sheep-owner that every practicable means shall be resorted to in order to *cure*, if possible, or, what is much better, to *prevent* the appearance of this disease, if such can be accomplished.

Now, we may at once say we have no faith in any so-called cures for rot, because by the time it begins to be so much developed as to attract attention the disease is beyond the power of medicine. We must endeavour to prevent the occurrence of the malady; we may delay its progress when sheep are even affected by it, but we

cannot actually cure it—we cannot eradicate it so as to restore the affected animals to a pristine state of health.

Excessive moisture stagnating in the soil is a predisposing cause of rot. We are not alluding at present to the scientific view of the question, embracing the history of those animalculæ which exist in the livers of rotten sheep: those who are desirous of following out this part of the subject will find it fully and ably discussed in Professor Simonds' admirable lecture, delivered at a weekly council meeting of the Royal Agricultural Society of England, and reported in Nos. 17 and 18 of our volume for 1861. We are considering the subject practically, and for that reason we refer in the first place to the effects produced by excessive moisture, particularly stagnant moisture in causing rot among sheep. The removal of this agent in the development of the disease is entirely within our reach. When we drain the land we lessen the probability, if we do not actually remove altogether the possibility, of rot making its appearance on such land. When we say this, we refer to sheep which are bred and kept on drained land. It is true, cases of rot may and do occur on pastures which are either artificially or naturally dry; but if so, we may be certain that the disease is confined to sheep which have been bought in, or brought from another place where draining has been neglected; unless, indeed, some rotting spot has been left unnoticed and undrained in the range of pasture. We know this from experience. We have bought sheep early in autumn—sheep which were apparently perfectly sound when purchased, yet, although put on sound pasture, those sheep have rotted and died to such an extent that very few remained alive out of the lot at shearing time. At the same time, sheep bred on the ground, and others brought from healthy localities, although grazing along with the diseased sheep, and treated in every respect in the same manner, remained perfectly sound. The seeds of the disease were laid in those sheep prior to their purchase, although the disease itself had not become sufficiently developed to attract attention.

Referring to the death of sheep from rot during the winter and spring months, Prof. Simonds remarks that the most dangerous period for sheep is about midsummer, particularly when there is much rain with the elevated temperature of that season. It is at that period the foundation is laid of the disease which terminates, some months after, in a change from a thriving to a wasting state of condition, in jaundice-like appearance of the skin, &c., in the accumulation of that particular swelling under the lower jaw which invariably accompanies this disease, and in all the other tokens of an unhealthy constitution ending in death. We feel convinced that Prof. Simonds' views are correct, and it shows the necessity of avoiding hasty conclusions when rot does make its presence apparent during the winter months.

But as draining has been proved to be effectual in preventing the disease—nay, more, in changing the character of the districts which at one period were notoriously unsound—it is evident that every flockmaster should strive to have his land drained, and thus permanently secure the health of his sheep. Through draining, as we usually understand the phrase—that is, drains 42 or 48 inches in depth, having conduits of pipes or broken stones for the passage of the water—is the system which must be adopted when the sheep pastures are combined with tillage operations; but when this is not the case, a more simple and more cheaply executed mode of draining will suffice to carry off excessive moisture and lessen or remove the danger from rot. Surface draining has proved of immense service in sheep-rearing districts, improving the climate, increasing to a great extent, the production of nutritious grasses, and not only lessening the annual mortality, but enabling the stock-masters to keep more sheep than they could do whilst the land remained in its natural condition.

These drains are from 16 to 18 inches in depth, 20 to 24 inches wide at the top, and 6 to 8 inches wide at the bottom. Double drains—that is, the drains made for the purpose of carrying off the accumulated water from drains of the foregoing dimensions to the nearest main drain or rivulet—are 30 inches wide at the top, 18 inches deep, and 12 inches wide at the bottom. The distance at which the drains are cut from each other depends on the nature of the land, and may vary from 6 yards to 60, according to circumstances. The cost of cutting surface drains of this kind ranges in Scotland, where the system is much practised, from 1d. to 2d. per seven yards, the double drains being just double the price of the minor drains, each seven yards of the double drain counting as fourteen yards of the other. The acreable cost, therefore, is comparatively trifling, amounting, at say 20 yards distance between the drains, to from 3s. to 6s. per statute acre. Mr. Cullen, of Corry, Co. Lincoln, finds “that open drains, 50 feet apart, may be formed 2 wide feet at top, 10 inches at bottom, and 15 inches deep, at a cost of “about 7s. 6d. per statute acre.”

Yet, trifling as the cost of such draining is, the benefits resulting from it are immense. Mr. Cullen's experience is “that land so drained (after two years) will be worth double, treble, or even fourfold more than when undrained;” and Mr. Latham, of Alberchald, Inverness-shire, in a prize report “On Draining Sheep Farms,” which appears in the recently issued part of the *Transactions of the Highland and Agricultural Society*, illustrates the advantages of surface draining, with reference to rot, in the following manner:—

“Striking instances of the cause and cure of this disease have come under my observation of late years. On an adjoining farm its ravages were very serious previous to the marshy ground being drained, but as soon as this was accom-

plished the rot gradually disappeared, and the sheep became, under careful management, a sound and superior stock. Now, however, after being open for thirteen or fourteen years, these drains, which were cut much too shallow at first, are gradually filling up, and the rot has returned.”

Open surface drains, we must observe, should be scoured out once in every three or four years, and if this is done the drains will be kept always in good working order, at a trifling expense.

If pastures which contain much stagnant moisture are of such a nature as to cause rot, it is certain there are some other points in management which tend to foster the development of the disease. Some of the most prominent may be summed up in one word—over-stocking—because this not only includes the want of a sufficient amount of nutritious food, but also the *fouling* of the pastures—a circumstance which is highly detrimental, whenever it occurs, to the health of sheep. To confine a lot of sheep on a limited piece of pasture for months, without changing them to another field where they can get a clean bite—that is, where they are entirely dependent on the pastures—is about the worst treatment sheep can receive. Yet we often find it practised—we find lambs, when weaned, put on a very indifferent piece of grass, kept there during the autumn and during the winter, without being shifted for a single day; and when such is the case, we never feel surprised to learn that there are “plenty of skins” lying about the owner's premises. Dirt and starvation are sure means of bringing on disease on the human subject, and dirt and starvation are just as certain to bring on disease and lead to death among sheep. We have heard of pasture lands which bore a sound character—where rot was, in fact, unknown—until the flocks were increased beyond the numbers which the land previously carried, and no sooner was this done than rot appeared, nor was the disease banished until the flocks were reduced to the former complement.

Professor Simonds shows that a generous diet will stay the progress of rot, if it will not actually prevent its appearance. Alluding to sheep in the earlier stages of the disease, he says:—

“If the simple plan of protection with nutritious food is persevered in for some time, you may often save your animals. I did that,” he further says, “many years ago, I purchased a number of rotten sheep: I gave them no physic of any kind, but merely kept them in sheds during the winter time, fed them with corn and cake, giving them the most generous diet I could; and I not only prevented the further progress of the disease in several of these cases, but I even made the animals accumulate flesh, and they went into market in the following spring, forming pretty fair meat for the people. This shows what can be done by generous diet and a protection of the animals.”

In the course of his remarks, Professor Simonds showed that he still followed the same practice when apprehensive of rot. Referring to 1860, he said:—

"Now, what have we had in the past season? We have had a very wet summer. I had a number of sheep, and foresaw what was coming. I said to some of my neighbours, 'We shall have a great deal of rot this year;' and I thought I would attempt, if I could, so far as my own sheep were concerned, to save them. What did I do? The sheep were on wet meadows, up to the fetlock joints, nearly every day, and nobody could avoid it. But at midsummer I began to feed the lambs and sheep with corn and nitrogenized food, giving them with every meal a small quantity of salt. I continued that plan during the autumn, and I have the satisfaction of saying that I do not believe at the present time [April 1861] I have one of those lambs affected by rot. I kept killing them week by week to watch their progress."

Before concluding his lecture, he again returned to the advantages derived from the use of nitrogenized food—that is, food which forms blood and flesh, not fat—and wound up his remarks in the following manner:—

"I again say, that if we commence at midsummer, and continue the treatment through the dangerous period of a wet season, we may do a great deal in the prevention of the disease. And I may go further, and say that even on farms where we have what are called rotten pastures, on which sheep are placed, they may be preserved to a very considerable extent, simply by giving nitrogenized food and salt, to destroy those creatures within the stomach, and to prevent their final change, alternating with the salt a tonic, invigorating agent, such as sulphate of iron. I do not depend on the salt alone—far from it; but it is a valuable agent, and its value depends more upon putting these things into salt water, as it were, in the stomach, than anything else. This is the course I recommend. You have to look to the condition of the liver in a wet season; you have to look to the necessity of laying the foundation for a good quality of blood, by giving these animals nitrogenized food, and throwing sulphate of iron into the organism. . . . This is the reason why sulphate of iron should be employed. It should be given in fine powder, and in doses of about half a drachm a day; not, however, that a larger quantity would be prejudicial. The sheep should be divided into small lots; and if you have about a score feeding in one trough, there should be ten drachms of sulphate of iron mixed with the food for the day: and then, if one should get a little more, and another not quite so much, it will be of very little importance."

The publication of Professor Simonds' lecture drew out a letter from "A Yorkshire clay-land farmer," which first appeared in the *Mark Lane Express*, and was transferred to our

columns in the 18th number of last year's volume—page 231. The writer of that letter had suffered for many years from rot, owing to the "marshy nature of the soil" of his farm "and poverty of the herbage."

Twelve years ago he had commenced giving his sheep "about one gill of fine old dry barley each during the autumn and early part of spring," and so satisfied was he with the results, that he persevered in the practice during all the twelve years, having kept his sheep in perfect health by means of this more nutritious diet than the "poverty of the herbage" of his farm could have supplied them with. This is precisely the same principle as that upon which Professor Simonds acted, "for fine old dry barley" contains a considerable portion of nitrogenized matter.

If, therefore, we are desirous to ward off that fatal disease which we have been discussing in these brief remarks, we must make up our minds to relieve the pastures from the superabundance of moisture with which they are saturated, and which, at present, remains stagnating in the soil; we must stock our pastures moderately; we must protect our flocks as much as possible from the inclemency of winter; we must feed them on generous diet, thus "laying the foundation for a good quality of blood;" and when we have fulfilled all these conditions, we may rest assured that if we have in future "pleaty of skins" these will be in their proper place—on the outside of good, healthy, living bodies.—*Irish Farmers' Gazette*.

## Agricultural Intelligence.

### Spring Shows.

We are informed of the following Shows to take place this Spring. We request secretaries of Agricultural Societies to inform us of the date of their exhibitions at as early a date as possible, so as to admit of publication in time to be of use to those interested:—

Fullanon, Logan, and Hibbert Agricultural Society, at Mitchell, April 2.

West Riding of York Agricultural Society, at Weston, April 23.

King Township Show and ploughing match; at Kettleby, April 22.

Reach and Scugog, at Epsom, April 29.

Pickering, at Duffin's Creek, April 30.

West Gwillimbury, at Bond Head, April 30.

Brant Township, County Bruce, at Walkerton, April 28.

County Peel, at Brampton, May 1.

North York, at Newmarket, April 30.

County Halton, at Milton, April 23.

Walpole, at Humstreet's Hotel, Stage Road, April 16.

- Rainham, at Rainham, April 18.  
 Western Branch, Haldimand, at York, April 23.  
 County Haldimand, at Cayuga, April 24.  
 County of Lincoln, at Grimsby, April 22.  
 Hamilton Horticultural Society, 1st Show, May 24.  
 East Middlesex, at London, April 29.  
 Lobo Township Society, at Mr. E. Cutler's, April 19.  
 County of Norfolk, at Simcoe, April 9.  
 West Middlesex, at Strathroy, April 24.

### Removal of Mr. W. H. Lock.

Our readers will regret to learn that Mr. W. H. Lock, of Yarmouth, Elgin, the well known agriculturist and breeder of Devon cattle, has left this Province, and has taken up his residence near Urbana, Champlain Co., Illinois. Mr. Lock has been the most successful breeder and exhibitor of cattle in the county, and has taken more prizes for his Devons than all the other breeders combined. Mr. L. imported the stock, six in number, fourteen years ago, and at this time the progeny are to be found scattered all over the Province. He has bought a farm of 1,300 acres of land, 800 acres of which are improved, 300 in grain, and 200 in wood. Besides this, he has rented 500 acres. He took with him seventy-eight head of his fine Devon stock; one hundred pure bred sheep; thirteen horses; six hogs of the finest quality, besides a large assortment of implements. His wife, three sons, and one daughter have gone with him. Upon enquiry as to the cause that induced Mr. Lock to leave we find, that he thought that by removal to the States he would be less heavily taxed than in Canada—a most erroneous idea, for in addition to the ordinary State taxes, at all times heavier than similar imposts in Canada, the cost of the war has yet to be paid, and the landed interest will naturally be the one on which the charge will principally fall. We are sorry to lose Mr. Lock, sorry that so much valuable stock has gone with him, and sorry that so far as taxation is concerned he will find that he has jumped out of the frying pan into the fire.—*London Free Press.*

### Horticultural.

#### Fruit Prospect in Niagara Township.

EDITOR AGRICULTURIST:—As the fruit crop forms an interesting topic for inquiry, your readers in Toronto, and the cities north of the lake, will be glad to learn, that up to this date, the prospect of peaches is all that we could desire. The fruit buds are uninjured by the frost of last winter, and the cold

weather of March, has retarded the swelling of them, and as there was no crop last year, the trees are in fine condition, to produce an abundant one this, if not injured by the late spring frosts. But as a general thing we do not apprehend much danger from this cause. The cold winds from the lake greatly retard the opening of the blossoms, and often prevent a frost near the lake shore, when a few miles back every thing is cut off. It is seldom that we lose our peaches by spring frost. The greater danger we are exposed to, is that of the buds not being sufficiently ripened in the fall, or by being pushed too forward by the late warm moist weather of autumn, as was the case last year. In such cases a few degrees below zero is sufficient to destroy them, while in a proper condition they will bear even twenty degrees below zero with impunity. I am glad to say that there are several large peach orchards in this vicinity that will be in good bearing order in one or two years more, that will afford you a supply, even if our friends across the river should be excluded by the repeal of the reciprocity treaty. In the last two or three years a great number of trees, principally apple, pear, and peach, have been planted in this township, more particularly that tract lying along the river and lake shore from Queenstown toward the city of Hamilton, which may be styled the fruit garden of Canada, *par excellence*. More especially so for the supply of the large cities along the lake and the river St. Lawrence, enjoying as it does an easy communication with them all; which is much more favorable as well as cheaper than railroad transportation.

As the season for planting orchards is near at hand, I would earnestly entreat those intending to put out trees to plant no more than they can well attend to. It is not necessary that land for orchards should be of the very richest description, nor yet is it necessary that the trees should be over fed by abundant applications of manure. Trees, like children, can be killed by kindness, but this is the exception not the rule. Any good wheat land will do for apples or pears; it is all the better if it has a mixture of clay in it. And all good corn land will produce good peach trees, climate being favourable. Of course good surface drainage is necessary, and under drainage highly advantageous, to the successful cultivation of fruit or any other crop. Subsoil plowing is a very great benefit to a young orchard, and should be done before planting, as it can never be so well done afterward. Let any one be assured that fifty trees well planted and cared for are worth more than five hundred stunted, moss covered ones, and in ten years give more bearing trees.

It is really distressing to see a lot of young

trees struggling for existence in a field of blue grass or Canada thistles, browsed off by cattle or barked by sheep, while it is indeed a pleasure to see a thrifty young orchard growing up under one's careful management, and in a few years it will repay any generous treatment it may have received. But a neglected orchard is a subject of constant reproach and always ends in pecuniary loss.

I am glad to see such active exertions being made to establish a fruit growers' association for Upper Canada. It is a society eminently required for the wants of the country, and I feel confident from the names already connected with the enterprise that it will prove a success. The information that it has already diffused in regard to some fruits being hardy in certain localities and not hardy in others, is especially interesting to those intending to plant, and if attended to by them may save much expense and disappointment.

Since writing the above we have been visited with a very severe storm of sleet accompanied with a high wind. That veritable individual the "oldest inhabitant" never recollects of so much ice being on the trees, small twigs of last year's growth were loaded with icicles of an inch and a half in diameter. Of course such a load swayed by a heavy wind made great destruction among trees, but the older peach trees were the greatest sufferers, I think fully one half the bearing wood of such trees is destroyed, while the younger ones though not so badly broken are sadly mutilated.

R. N. BALL.

Niagara, March 20th, 1862.

### On the Failure of the Apple Trees in the neighborhood of Montreal.

*A Communication to the Committee of the Natural History Society of Montreal.* By JOHN ARCHBOLD.

(From the Canadian Naturalist and Geologist.)

The failure of the apple trees in the neighborhood of Montreal, and I believe in all the Island, is a sad calamity as regards domestic luxury, as well as in a commercial point of view. I have seen Montreal in its palmy days of apple-growing, export its thousands of barrels of Pommes Grises, Bourassas, and Fameuses. These were the principal sorts sent to Europe, the refuse of which as well as the great quantities of the wild apples, that is apples from seedlings, always found a ready market at Quebec and the ports below it, at remunerative prices. With these facts before us, it is not to be wondered at, that strict enquiry should be made by all who feel the least interest in the culture of the apple, as to the cause of its decay. I have been a resident in Montreal since 1832, and for the last twenty-five years have lived on the south-eastern slope

of the Mountain, on the Cote St. Antoine road, and have acted in the capacity of gardener at Mount Pleasant, the then residence of the late Joseph Savage Esq.; also at Rosemount, the residence of the Hon. John Young, and subsequently at Forden, the residence of Capt. R. T. Raynes and of the late Charles Bowman Esq.; one of the most zealous friends and supporters of Horticulture, in his day, that Montreal could boast of. All these places were noted for the production of fine varieties of the apple, the pear, and the plum. The latter place, Forden, in particular, used to yield about fifteen years ago, from 1,000 to 1,500 lbs. of fruit, but the last three years have made sad havoc with the trees, and unless some reaction in the growth take place, there will not be one of the old trees living, three years hence. I noticed the decline of some sorts of the apple twenty years ago. I had a talk with the late Henry Corse Esq., about that time, on the failure of the Early Harvest apple, and he was under the impression that it was then extinct about Montreal, but I convinced him that it was not, for in each of the above mentioned places, I had seen trees of the Early Harvest which gave from three to four barrels of good apples, but these few trees are, I have every reason to believe, now gone. There were also the Ribston Pippin, (much on the decline these last ten years,) the Keswick Codlin, Hawthornden, Grant's Major, John Richardson; but these and some others, I always looked upon as being tender, from the softness of their wood, which is not nearly so hard as that of the Bourassa, Pomme Grise, and Fameuse, and therefore, do not wonder at their destruction. These latter sorts have, however, for the last ten years been declining in vigor of their growth, and size of their fruit. I was for some time under the impression from what I could learn from some gardeners, and other cultivators of fruit, that the above named three sorts of apples, would not bear fruit in any other locality than in the Island of Montreal, but that impression was completely removed on visiting the Provincial Exhibition held at Brantford, C. W., some years ago. I saw there as fine specimens of the Bourassa as Montreal could produce in its best days. At Hamilton I also visited some of the gardens, and there to my surprise, I found the Pomme Grise, Fameuse, and Ribston Pippin, growing side by side, and loaded with fine fruit, with not the slightest appearance of decay. These remarks, however, are by the way; the point of discussion at present is the cause of the decay in the apple trees in the vicinity of Montreal. There will, no doubt, be a great many opinions put forth on the subject, and some light will, I hope, be thus thrown on both the cause and the cure. Were the decay confined to one place, one kind of soil, or one mode of pruning or culture, there would be less difficulty in discovering both the cause and cure, but when we find the decay in one fell swoop,

taking off the whole of the young orchards that have been planted within these fifteen or twenty years past, and that even the old *savage*, as the Canadians call it, that has stood the severity of the winters for the last fifty years, is suffering the same fate, the difficulty of giving an opinion is all the greater. When also it is observed that apple trees both in the most sheltered nooks and on the bleakest exposures, on the best alluvial soil, and on the gravelly and limestone rock, all alike share the same fate, the necessity of careful consideration is much increased. I noticed in several of the apple trees, after the severity of the winter three years ago, that many of the large limbs became disordered by their cellular tissues not admitting that uniform and free flow of sap to the outer extremities of the branches, which was necessary for healthy growth. The consequence was, that there remained in the trunk an overflow of sap, and some very severe freezing nights coming at the time, the sap froze, and caused the outer bark to burst; the trunk soon after presenting a black and decaying appearance. This is one of the causes to which I attribute the decay.

I have also observed in gardens and orchards, at a season when the trees are in full vigour of flower and foliage, that they have been completely denuded of their leaves by the ravages of the caterpillar; thus being left bare to the influence of a June sun, their health and vigour were seriously impaired. I have observed that trees which suffered so, for two years in succession, hardly ever recovered from the effects of it; this is one other cause to which I attribute the decay of the apple. To avoid injury to the trees, care should be taken as to the time of pruning. When this is done in the beginning of March, or, as is sometimes the case, before that time, and wounds are left bare, without any cover or protection, the influence of a hot sun by day, and hard frost by night, is such, that these wounds emit a portion of the sap, and cause the parts affected to become black, a sure forerunner of decay. In my humble opinion, that work should be deferred till later in the season. My reason for forming this opinion is, that I have observed in my practice of budding, which commences about the middle of July, for stone fruits, and continues all through August for the pear and the apple, having to cut and prune the stocks to a considerable extent, I always found the wounds, at that season, to heal up very quickly, and leave no trace of black, such as might be seen in early spring pruning. Another cause of decay, seems to me to be some kind of atmospheric agency, for I have frequently noticed a portion of the branches of apple trees, becoming black in parts where there were no wounds. Sometimes at the junction of the lateral branches with the main branch, and sometimes near the outer extremity of the branch. Some persons attribute the appearance to lightning, but that appears to me rather

doubtful, for although thunder and lightning are common in the summer months, in Canada, I never noticed any parts of apple trees to be blackened to the extent they now are, until these last four years past. There might, indeed, occasionally have been symptoms of decay in some trees, and in certain localities, but the cause in such cases was easily accounted for. This commonly occurred when trees were planted in hard blue sub-soil, saturated with water at all seasons of the year, without the least attention being paid to drainage. On consulting any of the British authors who have written on the culture of the apple, they will all be found to agree that the soil should undergo a thorough preparation previous to planting, and that it should be trenched at least to the depth of two feet. If such preparation is an essential in such a mild climate as Great Britain, it is much more so in Canada, where we have frequently such a long continuance of drought in the summer, and severe frost in the winter. I have often been struck with the short life of the apple trees about Montreal. There was an impression made on my mind, in early life, that the apple was a long lived tree. I have known apple trees in the west of Ireland, in the neighborhood of the town of Sligo, to attain the age of 150 years, and then to be bearing good crops of apples. I also find that A. J. Downing, one of the most reliable and best American authors, in writing on the long age of the apple tree, says he saw in Rhode Island, two trees 130 years old. He, however, reckons our fine garden sorts to live only from 50 to 80 years. Now, I question if we could find about Montreal any of our fine garden sorts half that age, that is 40 years old. He also strongly recommends trenching the soil, and says it adds greatly to the long life of the trees. I must confess that I have not seen that proper attention paid to fruit trees in the neighborhood of Montreal which they require. I have seen, in many cases, trees planed on the green sward, without any other preparation than simply making a hole and putting in the tree; leaving it afterwards to take care of itself. In such cases the result may be easily conjectured. In taking up numbers of both pear and apple trees, the heads of which were dead, I have found that their roots were generally perfectly sound, not showing the least symptom of decay below the surface. The cause of decay does not therefore lie with the root.

The question often occurs to me, shall we ever see Montreal producing the fine fruits that it had twenty-five years ago? The markets were then filled to overflowing with the finest varieties of the plum and the pear, and a pretty good quantity of the peach and apricot, of open wall culture. Now there is no such thing to be found as a good Bon-chretien pear, or an Autumn Bergamot, or a Burmese Spruce, or yet a luscious Bolman's Washington plum, or a Greengage, or even a coarse Magnum Bonum;

and but seldom will you find a good basket of the common wild red plum of the country. I have also noticed a decline in the vigour and growth of several other plants, these last few years past, in comparison with what might have been seen twenty years ago. Then I saw the gardens about Montreal produce enormous crops of melons, with very little care or attention; now it is uncertain if you can get a good crop with all the care you can give them. I have also seen good crops of grapes raised in the gardens and have myself raised at Mount Pleasant, good crops of the Sweet Water and Black Cluster in good condition, in the open ground. Then there was no such thing as the mildew, or the nip, as it is now; nor was that troublesome pest, the curculio, known about Montreal. Yet with all these facts before us, it will not do to be idle lookers on; better to be up and doing. I would suggest that any man possessed of land, whether little or much, should plant trees according to his means, and let what is planted, be planted in the best possible way, and under the best conditions of the soil and culture. He may then hope for good results in time to come.

These few remarks, hastily penned, are respectfully submitted to the Montreal Natural History Society.

Forde, 6th January, 1862.

## Fruit Growers' Society of Western New York.

### ANNUAL MEETING.

The Fruit Growers' Society of Western New York held its Annual Meeting at the Court-house, in the city of Rochester, on the 8th ult. The meeting was large, and its discussions interesting and harmonious.

#### BEST FORM FOR AN APPLE TREE.

*V.—What is the best form of an Apple tree, and which is the time for pruning?*

Mr. SHARP thought he might not agree with others in his views of pruning. Would head all fruit trees low. Branches pruned near the ground are more vigorous and stocky than those formed further up the main stem. They show a disposition to ascend instead of running out horizontally, make a good spreading top, and can bear more weight without injury. Trees trained in this way are also less exposed to the winds. This is particularly the case with pears.

Mr. FISH agreed with Mr. Sharp. Branches pruned near the root are stronger than those formed six or seven feet from the ground.

Mr. HOOKER considered the question a difficult one. Trees grow naturally of all forms. The Northern Spy has an upright growth, Greening

crooked and drooping, while the Baldwin makes a round-headed tree. Cut out the young wood from a Tompkins County King, as is desirable for a Northern Spy, and soon there would be no bearing wood left. The variety requires shortening, while the Northern Spy requires thinning out. It is well to study the habits of trees, for, do the best we can, they have their peculiar shape.

Mr. MOODY said they had come to some system of culture that would suit farmers. Farmers would not use the fork. He found no evil from ploughing. Commence ploughing when the trees are young, and the roots will not come near the surface. Would form heads four or five feet from the ground. Some tender trees have the bark injured by the sun in winter. This is prevented by growing branches low.

Mr. BEADLE said the climate in which trees are grown may have a good deal to do in determining the form of the tree. Mr. MOODY spoke of the sun burning the trunks of trees. Had seen the same frequently in Canada, the bark injured for seven or eight feet up the trunk. Thought it the effect of the sun followed by hard frosts. By keeping the head low the trunk is protected. Never saw any ill effects from heading trees low. In Canada they have severe south-west winds. Every tree leans. The main crop is blown off high trees. Mr. B. would not use a plough under or near the trees, in an orchard. The roots like to come near the surface for air and dew. Use a cultivator.

J. J. THOMAS had made a good deal of observation in the length of roots. The radius of the roots is equal to the height of the tree. If the tree is twenty feet in height the roots will extend twenty feet from the trunk in every direction. Mr. T. enquired if any one had ever known injury to result from ploughing an orchard? The tearing of the roots a little, he thought, not so injurious as neglecting to stir the soil. Apple roots, many of them, go down low, but peach roots lie near the surface.

Dr. SYLVESTER said it is necessary to shade the trunks of trees, and it is also necessary to keep the tree growing to obtain good fruit. To effect this it is necessary to keep the ground well cultivated, and it is hard to do this if the head is formed very low.

At the close of the discussion on this subject members were requested to prepare and leave with the Secretary a list of the best six summer, the best six autumn, and the best twelve winter varieties. The following is the aggregate vote:

#### Best Six Summer—Two Sweet.

|                  |    |                |    |
|------------------|----|----------------|----|
| Red Astrachan    | 12 | Summer Pernaia | 2  |
| Primate          | 10 | Early Joe      | 3  |
| Early Harvest    | 8  | L. well        | 1  |
| Early Strawberry | 8  | Banoni         | 8  |
| Keswick Codlin   | 2  | Sweet Bough    | 12 |
| Summer Rose      | 5  | Golden Sweet   | 8  |

*Best Six Autumn—Two Sweet.*

|                            |    |                          |   |
|----------------------------|----|--------------------------|---|
| Colvert.....               | 2  | Munson Sweet.....        | 7 |
| Twenty Ounce.....          | 10 | Fall Tenetting.....      | 1 |
| Gravenstein.....           | 9  | Twenty Ounce Pippin..... | 1 |
| Duchess of Oldenburgh..... | 7  | Pumpkin Sweet.....       | 1 |
| Porter.....                | 7  | Maiden's Blush.....      | 1 |
| Jeffies.....               | 8  | Fall Pippin.....         | 2 |
| Pomme Royal.....           | 3  | Sylvester.....           | 1 |
| Beauty of Kent.....        | 2  |                          |   |

*Best Twelve Winter—Two Sweet.*

|                            |    |                       |   |
|----------------------------|----|-----------------------|---|
| Rhode Island Greening..... | 13 | Minister.....         | 1 |
| Tompkins Co. King.....     | 12 | Smith's Cider.....    | 1 |
| Northern Spy.....          | 12 | Norton's Melon.....   | 1 |
| Baldwin.....               | 12 | Canada Reinette.....  | 2 |
| Tolman Sweet.....          | 14 | Bine Parnain.....     | 1 |
| Spitzenburgh.....          | 8  | Raul's Janet.....     | 2 |
| Golden Russett.....        | 5  | Seek-no-further.....  | 2 |
| Roxbury Russett.....       | 7  | Green Sweet.....      | 3 |
| Peck's Pleasant.....       | 7  | La Tes Sweet.....     | 5 |
| Yellow Bellflower.....     | 7  | Cooper's Market.....  | 2 |
| Pomme Gris.....            | 4  | Cranberry Pippin..... | 1 |
| Canada Red.....            | 5  | Ribston Pippin.....   | 1 |
| Swaar.....                 | 6  | Bailey Sweet.....     | 3 |
| Red Cheek Pippin.....      | 3  | Jersey Sweet.....     | 3 |
| Wagener.....               | 6  | Pound Sweet.....      | 1 |
| Belmont.....               | 2  | Hill Sweet.....       | 1 |
| Fameuse.....               | 7  | Pomme d'Or.....       | 2 |
| Rambo.....                 | 5  | Jonathan.....         | 1 |
| Vandervere.....            | 1  | Mother.....           | 2 |

Mr. BARRY announced that among the distinguished fruit growers present, he was happy to observe the Rev. J. Knox, the celebrated Fruit Farmer of Pittsburgh, who has two hundred acres in fruit, and fifty acres in strawberries. The President requested Mr. K. to favour the meeting with an address.

Mr. Knox stated that as he had more experience with strawberries than any other fruit, and without pretending to make an address, he would give the members the benefit of his experience in strawberry culture, treating of soil, preparation of soil, cultivation and varieties. He considered a rather light clay soil best for strawberries. The first work in its preparation is through drainage, next breaking up or pulverizing, from twenty to twenty-four inches in depth. This is effected by the plough alone. First use an ordinary plough, with two horses, followed by Mapes' lifter, a kind of sub-soil plough, with two yokes of oxen. Give the ground several ploughings in different directions, until it is well broken up and pulverized. Could produce two or three very good crops on land ploughed in the ordinary way, eight or ten inches, but on that two feet deep could obtain ten or twelve crops in succession. Strawberries do not require much manure. Any good wheat or corn land is good enough for strawberries. Plants in rows thirty inches apart, and the plants ten inches apart in the rows, making twenty thousand plants to the acre. When he commenced strawberry culture, Mr. K. ploughed between the rows, but latterly has discarded all implements in his strawberry plantations, except the hoe. Weeds are taken out by hand. The less soil is disturbed after planting the better, as the whole ground is covered with a network of small, fibrous roots. Never allows the vines to bear the first year planted, but picks off all the fruit stems and runners, and removes the runners

every year that the plant is fruited. Prefers setting out early in the spring. Protects the plants in winter by wheat or rye straw, thrashed with the flail. Oat straw is not heavy enough, and blows off. Plants bear much better for this protection. The straw is removed in the spring, and placed around the plant's as a mulch, and helps a little towards furnishing manure. One half the straw is wasted each year, and needs to be supplied every autumn. Two tons to the acre is about the right quantity of straw to commence with, but after that, one ton of new straw each season will answer. Varieties that succeed in some soils and situations, fail in others. The Hovey is good in Boston, and Mr. K. had seen it good in Cleveland, but with him it never succeeded. Some varieties seem to run out after culture a number of years. Pistillate varieties do better when impregnated with some staminate sorts, than with others. On this subject he is trying experiments. The strawberry season ought to be lengthened. It is usually about three weeks, but with proper selection of sorts, can be extended to five weeks. The sorts Mr. K. liked best were the following:

EARLY.—Baltimore Scarlet, Jenny Lind, Burr's New Pine.

LATE.—Trollope's Victoria, Kitley's Goliath, Nimrod, Buist's Prize.

MEDIUM.—Brighton Pine, Boston Pine, McAvoy's Superior, Scott's Seedling, Moyamensing, Downer's Prolific, Fillmore, Golden Seeded, British Queen, Vicomtes Hericart de Thury, Wilson's Albany, Triomphe de Gand.

*The Apiary.**Ants.—To Keep Away from Hives.*

When hives are properly constructed, ants cannot get into them to propagate their young. They frequently, however, get into hives in consequence of not being properly constructed, and do much injury as they annoy the bees, injure the hive by eating into the wood, and will eat the honey if accessible. It is very little trouble to drive and keep the ants away from the hive, although much trouble has been experienced by many, for the simple reason that they knew no remedy. *To drive the ants away from the hive*, or out of their retreat, direct upon them a small quantity of the smoke of wood or tobacco. Each one will usually shoulder a number of their young, and "secede" instantaneously! *To keep the ants away from the hive*, apply, as soon as they have mostly disappeared, thinly in places where they frequent, with the feather part of a quill, the *spirits of turpentine*; they will not be seen again, in general, during the remainder of that season; but should they return, repeat the application. This preventive is very simple as well as efficacious; try it.—M. M. BALDRIDGE, in *Bee Journal*.

**PROFITS OF BEE-KEEPING.**—Mr. R. H. Davis, a practical farmer, and one of our subscribers, who has a large and well-managed farm at Larone, in Somerset county, furnishes us with the following notes relating to the profits of his small apary during the year of 1860. In the spring of that year, Mr. Davis had four swarms, which being wintered through, he valued at five dollars each, or twenty dollars. These four swarms sent out during the season ten new swarms, eight of which were worth in the fall four dollars each, or thirty-two dollars. The other two swarms had not honey enough to winter on. It was, therefore, strained and sold, (thirty pounds), as ten cents per pound, which amounted to three dollars. From the eight new swarms Mr. Davis sold two hundred and fifty-eight pounds of box honey, at twelve and a half cents per pound, amounting to thirty-two dollars and twenty-five cents. There was also some wax made, not taken into account. The old stocks of bees were reckoned at four dollars each in the fall, the same as the new swarms. This gives a clear profit of \$67.25 from four swarms in one season. Who can give a better account from so small a lot of bees?—*Maine Farmer.*

## Editorial Notices, &c.

**SECOND ANNUAL REPORT OF THE PROVINCIAL BOARD OF AGRICULTURE, NEW BRUNSWICK.**—We are indebted to Jas. G. Stevens, Esq., Secretary of the Board of Agriculture in the sister province, for a copy of the interesting volume under the above title. It contains a statement of the doings of the Board during the years 1860 and 1861; Essays on Agricultural subjects; Reports of Committees, &c. &c. Appended is the Report of the first Provincial Exhibition held under the superintendence of the Board, in 1861, from which we may learn that great progress has been made in Agriculture, manufactures, and arts, and generally in developing the great natural resources of the province, giving good grounds for sanguine expectations of the future. We shall be happy to hear of the continued progress of the agricultural, as well as all other important interests in the neighbouring province.

**FIFTH ANNUAL REPORT OF THE SECRETARY OF THE MAINE BOARD OF AGRICULTURE, 1860.**—We always welcome the Agricultural Report from the State of Maine, edited by the accomplished and able Secretary of the Board of Agriculture, S. L. Goodale, Esq., as amongst the most valu-

able of the publications which come to our table. Amongst the contents of this volume is placed the able treatise by Mr. Goodale on the "Principles of Breeding Domestic Animals," which we had previously received, and noticed in a separate form. Besides the usual reports of proceedings of the Board, and abstracts of returns from the Agricultural Societies of the State, there are also essays on Sheep Husbandry, Underdraining and Deep Tillage, Irrigation, Practical Entomology, &c. &c.

**COUNTY OF PETERBORO'.**—By the courtesy of the Rev. V. Clementi, President of the Peterboro' Horticultural Society, we are in possession of a neat pamphlet entitled "An Exhibit of the Progress, Position and Resources of the County of Peterboro', Canada West, Based upon the Census of 1861, together with a statement of the trade of the town of Peterboro';" by Thos. White, Jr. This little compilation makes a useful and convenient hand-book of reference for those interested in that county, and also contains some interesting information in regard to the progress of the new settlements in the rear of that part of the country.

Some of the above-mentioned publications have been received a considerable time, and we have to apologize to the donors for accidentally omitting to notice them sooner.

## Imported Thorough Bred Cattle FOR SALE.

**THE SUBSCRIBER OFFERS FOR SALE,** the whole of his lately imported herd of improved Short horns. Full pedigree for each, authenticated by reference to Coates's English Herd Book.

G. W. PHILLIPS,  
Ogdensburgh, N.Y.

## Fresh Garden, Field, & Flower Seeds.

FOR SPRING SOWING.

**JAMES FLEMING & Co**, Seedsmen to the Agricultural Association of Upper Canada, beg to inform their friends, and the Farmers of Canada generally, that their stock of Fresh Seeds is now complete and very extensive, embracing almost every kind of seed suitable for the country. The stock of Agricultural Seeds is large and well selected. The vitality of each sort is carefully tested, and their genuineness may be fully relied upon. A large stock of Peas, Timothy, and Clover:

Spring Tares,  
" Wheat,  
Black and White Oats.  
Swede Turnips, Purple top.  
" " Green top.  
" " Laing's Improved.  
" " Skirving's Improved.  
White Globe Turnip.  
Yellow Aberdeen "  
" Altringham "  
Waite's Eclipse Turnip.  
Stubble or Six Weeks "  
Mangel, Long Red.  
" Long Yellow.  
" Yellow Globe.  
" Red Globe.  
" New Olive Shaped.  
Sugar Beet.  
Field Peas, several varieties.  
Marrowfats, " "  
Barley, two and four rowed.  
Buckwheat.  
Indian Corn, several varieties  
Alsike and White Clover.  
American Orchard Grass,  
Kentucky Blue Grass.  
English Rye Grass.  
French Lucern.  
Cow and Rib Grass.  
Carrot, White Belgian.  
" Long Orange.  
" Altringham.  
Parsnip, Hollow Crowned.  
&c., &c., &c.

Also a full and general assortment of all kinds of Garden Seeds: a Catalogue of which, with directions for sowing, can be had on application. Agricultural Societies ordering Seeds, will be supplied on liberal terms. Country Merchants supplied with complete assortments of Garden Seeds on Commission, neatly put up in boxes of 200 papers each, for retailing at five cents a paper. Also a large assortment of Flower Seeds, embracing the novelties of the season.

No. 126 Yonge Street, Toronto.

March, 1862.

No. 8.

The Alderney or Jersey Cow.

The breed of cattle, termed Alderney, has long been known as belonging to the Channel Islands, a small group which lie near the shores of France, but pertaining to the Crown of England, being the sole remaining appanage of the ancient Duchy of Normandy.

For many years large numbers of these cows have been exported to England, where they are much esteemed for the peculiar richness of their milk, and the large amount of excellent butter which it yields. The breed somewhat varies in the different islands, but the animals belonging to it may be generally described as small and

ill-formed, particularly in reference to fattening. In this respect they exhibit a striking contrast to the larger and more widely diffused breeds, such as the Durham, Devon, Hereford, &c., &c.

"The cow is greatly below the male in strength and stature: her neck is thin, her shoulder light, her chest narrow, and the belly large. The limbs are slender, the pelvic bones prominent, the lumbar region is deep, the croup short and drooping, and the udder large. The muzzle is narrow, the horns are short, slender and curving inwards. The colour is usually of a light red or fawn, mixed with white; but frequently

individuals are black, mixed with white or dun, and sometimes cream-coloured. The skin is thin, and of a rich orange colour, and the fat, as well as the milk and butter, is tinged with the same colour. The animals are gentle, and somewhat delicate in constitution. Being small in size, the milk they yield is small in quantity, although fully in proportion to their bulk of body; and it is viscid and exceedingly rich in cream. In their native islands the steers are used for labor, to which they are better adapted than, from the slender form of the dam, might be inferred."

In these rich and picturesque islands land, according to French customs, is very much subdivided, and the agriculture resembles in many respects that of Belgium, that is, very garden-like. "The cow, in an especial degree, is the subject of the care of these island farmers. She is penned in a narrow space, and shifted to fresh spots of herbage several times in the day, and in the nights of winter she is warmly housed, and, when about to calve, is nourished with cider. Through all the year these little cows are to be seen in their patches of meadow, often under the shade of the apple trees, and so fastened that they cannot raise their heads to pull the fruit. In addition to their herbage, they are fed with lucerne, clover, carrots, parsnips, and the large Jersey cole, the leaves of which are stripped off as they grow. A value is here attached to the cow greater, perhaps, than in any other part of Europe. She is the resource of the household for food, and her surplus produce is a part of the returns of every farm. A Jersey man, it is said, will treat every animal on his farm with neglect except his cow. To preserve the purity of the race, an act of the insular Legislature was passed in the year 1789, and yet subsists, by which the importation into Jersey of any cow, heifer, calf, or bull, is prohibited under the penalty of 200 livres, with forfeiture of the boat and tackle, and a further penalty of 50 livres is imposed on any sailor on board who does not inform of the attempt. The animal itself is to be immediately slaughtered, and its flesh given to the poor."

The island of Alderney is too small to allow of any large exportation of these animals, the principal part of which come from Jersey, which exports about two thousand annually. These

are the small, fine, and handsome sort, the favourite colours of which are the dark tan, and the lemon and white. The *Guernsey* cow is larger, coarser, and harder, but there is not that dependence on the purity of the breed as in the Jersey cow. In Jersey, as before mentioned, no other animal is allowed, upon any pretence, in the island; while in Guernsey the law is not so stringent. Then the *quality* of produce is believed to be better in the Jersey than the Guernsey.

A recent writer of high authority remarks as follows:—"All Channel Island cows, and also very many from the adjoining coast of Brittany, are sold in England under the general name of 'Alderneys.' There seems to be important differences between the cows of the different islands. Those which are really bred in Alderney are the smallest,—then the Jersey ones; the Guernsey animals are the largest. There is a great jealousy between the islands about the superiority of their own cows. The Alderney people stoutly maintain the superiority of the animal which has (rightly or wrongly) given a name to the breed; whilst the contest between Guernsey and Jersey rages on hotly upon this moot point as upon many others. Whatever may be the rights of the question, however, it is certain that Alderney can spare very few cows for exportation. There are not 400 head in the island, and the number annually spared from this stock is under fifty. Jersey exported 1,138 cows and heifers in 1860; Guernsey not half that number. Many cattle are shipped at Brittany, and the skippers, calling at Jersey or Guernsey upon some pretence to get customs' papers there, bring their live stock on to England, and sell them for Channel Island cattle. This is a fraud, for they may be bought in Brittany at from £4 to £5 a head, but a genuine Alderney will fetch from £14 to £18. In spite of the enthusiasm with which the merits of the Alderney cow are supported by her admirers, there are some who maintain that in-and-in breeding has done its work in effecting a deterioration of the animal. They point to the fact that in Alderney, where the purity of the breed is most conservatively kept, the animals are smaller. They declare that in Brittany, by the system of in-and-in breeding, a race of diminutive cattle has been obtained still smaller

than the Alderney cow. As for the superior productiveness of the breed, they maintain that it does not exist, or that at least it is the result of constant pampering, such as would be quite inconsistent with an extended system of agriculture. Arguing in this way, they conclude the main merit of these cows is that they are beautiful little animals, whose chief attraction consists in their comparative scarceness; and that the high price which they fetch is due rather to a fancy than to any accurate valuation of their intrinsic worth. These opinions must be heretical to patriotic Channel Islanders, and are recorded, not because we agree with them, but because we have heard them upheld by persons who seemed entitled to attention. As for the charge of 'pampering,' one farmer's wife recommends a little cider to be mixed up and baked with bruised beans as the cow's food. In her opinion, it made them eat more heartily."

We are not aware that any of the Channel Island breed of cattle has been introduced into Canada, and but few, we believe, have found their way, as yet, into the United States. The cut prefixed to this article represents a cow imported from the island of Jersey, by Mr. Rowsell Colt, of Patterson, N. J. In England, these cows are principally confined to small dairies, belonging more particularly to amateurs or private gentlemen. One Alderney only among a dairy, or three or four cows, is found to materially improve the quality of the milk and butter. It is this tendency to convert the far greater portion of the food which they consume into the richest milk, that renders them so difficult to fatten. They are well worth a trial in Canada by private families who feel a special interest in the quality of the milk and butter which they consume; but great attention would be required during the severe weather of our winters with regard to feeding, cleanliness and protection.

#### Alsike Clover.

[From the *Irish Farmers' Gazette*. The Alsike is generally approved of in Canada, when it has been fairly tried.—Ed.]

Alsike clover (*Trifolium hybridum*), though introduced into the British isles nearly a century ago, and re-introduced several times since, has made but little progress in general cultivation as a forage plant. For many years it was chiefly cultivated as a curiosity in botanical col-

lections, but for some years back it has engaged more attention amongst the more enlightened of our agriculturists: for this purpose it has been cultivated from time to time by several; but from inattention to its *habitat*, so as to develop its excellencies, it has just as frequently almost been thrown aside, as not fulfilling the expectations formed of it.

It enjoys the name hybrid from the intermediate resemblance it has to the common red clover, *Trifolium pratense*, and white clover, *Trifolium repens*, which has given the idea that it is a hybrid or mule produced by a union between those plants; but in reality it is a perfectly distinct species from either, for though *Trifolium repens* and *Trifolium pratense* have been growing in close proximity for ages past in the British isles, there has been no instance on record where this species has been found or discovered in these countries. This fact, in our opinion, amounts to proof-positive that the plant in question has not been produced by hybridization, but that it is a perfectly distinct species.

It is reported to grow wild in Finland, Denmark, Sweden, Germany, France, Portugal, and Italy, and was first found growing with great luxuriance in ditches at Alsike in Sweden—hence the name of Alsike clover, given by some late introducers of the plant. Upon a close examination, it has not the most distant resemblance to *Trifolium pratense*: and it resembles *Trifolium repens* in but a partial degree. Its roots are fibrous and perennial, but the stem is not creeping and rooting at the joints like the white or Dutch clover; neither is the stem erect like red clover, but weak and branching; its leaflets are ovate, and slightly serrated; the flower heads are globular, and fixed on long peduncles; the colour of the flowers whitish and pink; and the seed vessels tetragonal. Having less deeply penetrating roots than red clover, it is not calculated for very dry soils or extended droughts. Being a more permanent plant than red clover, though it does not yield so heavy a crop, it is well suited for sowing in land that has become clover-sick, providing the land is deep and not too dry, its favourite soils being deep loamy and peaty soils, rich in vegetable matter, but stagnant wet is destructive to it. In such soils it grows to the greatest perfection, producing hay of the most nutritious description; retains its leaves, smell, and colour in curing; is reported never to become mouldy; and as either a hay or a green soiling crop is eagerly eaten by all descriptions of stock.

On rich, reclaimed moors or slob lands it is a most valuable plant, being much more permanent than red clover, and yielding a heavier crop than the white species. We saw this exemplified on the reclaimed slob land of Lough Foyle when the Royal Agricultural Society held their show at Londonderry, in 1858, very extensive breadths of it having been laid down

with this plant. It is therefore, highly useful and valuable on such land, producing both a soiling and a hay crop; while the white clover is of too prostrate and creeping a habit to be useful for anything but grazing. On the other hand, on dry arid lands it produces poorly, dwindles away, and finally perishes in drought; while the white clover retains its hold, and though it suffers in thin soils in point of drought, and, to all appearance dies, in very thin soils, it quickly recovers and grows luxuriantly when rain sets in, so that it depends on the judicious selection of the soil whether the cultivation of Alsike clover or any other plant becomes remunerative or not.

We have already stated that it was found growing luxuriantly in ditches at Alsike. This is a good guide to its cultivation, and we may safely infer that such a situation is its natural *habitat*, and that it requires a rich, sappy soil to bring it to perfection, but it must not be wet. On deep, alluvial soils and rich, well-drained, moory soils, it is a most valuable addition to our foddering plants; but on high, dry, or thin lands, richly laid down, though it may do well for a time, it will run out and lead to disappointment.

### Kohl Rabi.

[This valuable root has been successfully grown in different parts of Canada, and deserves to be more generally known. It is important that it should receive a fair and extensive trial. The subjoined remarks from the *Irish Farmer's Gazette* will be found interesting and suggestive.—Eds.]

Another farming crop that should be attended to at once, and should be more extensively cultivated than it is, is the kohl rabi. It is a long time since this plant has been introduced into these countries, more as a garden curiosity than anything else; but as a useful feeding plant for cultivation in the farm it has been very tardy in making its way. It thrives in almost any soil and in almost any climate. In India it is in much request as a rich and delicate garden esculent, and in many of the European continental countries it is in high esteem for feeding milch cows and other cattle. It is also most useful for feeding sheep, is perfectly hardy, and stands any amount of frost. It is the only plant that has been found really useful in filling up the blanks amongst swede turnips, and where that crop has been cut off by the fly it is the only plant that gives a certainty of a full crop by transplanting it, which is much better than sowing swedes or any other turnip again. For this purpose it should be sown thickly in beds as soon as pos-

sible; the earlier the better, so as to have good strong plants to put out by the end of May or early in June. By giving sufficient space the globular heads produced will weigh from 6 to 10 lb. each and upwards; the rows should not be nearer than 2½ feet, and the plants two feet apart in the rows. They may also be sown in drills any time in May, and treated in every way the same as turnips. Kohl rabi is not only perfectly hardy, but it bears accidental injury better than swedes; for while the latter, when wounded, quickly rots away, the former still remains sound. Experiments have been made by cutting and hacking both kohl rabi and Swedes side by side to ascertain this, and while the Swedes rotted away, the kohl rabi seemed nothing the worse. Hares and rabbits are particularly fond of the kohl rabi, and when found growing in the same field they reject everything else in favor of it while it lasts, as we repeatedly witnessed; and upon our recent visit to Rocksavage, the seat of C. Kenny, Esq., all the kohl rabi then in the fields was completely scooped out. Besides being a very superior farm crop, its leaves as well as bulbs are particularly useful in the kitchen; the former being sweet and palatable, and the latter, when well boiled and well macerated with milk and butter, being an admirable substitute for mashed turnips, and when advanced in the season being free from woody fibre that renders turnips useless as a table vegetable at that time of the year.

### The Course of Agriculture in the West.

Causes influencing the Present Prices of Corn—Freights to the Sea-Board—The East may compete with the West in the Production of this Staple—Northern *versus* Southern Illinois—Cotton Growing.

CHAMPAIGN, ILL., Feb. 1, 1862.

As there is an intimate relation existing between the producers of the East and the West, it is right and proper that they should be posted as to each other's doings. Within the past few years great changes have been made in the staple products of the country. The whale fisheries, once so extensive and profitable, were ruined by the discovery of lard oil, which, by the cheap corn of the west, could be procured at a cost below that of catching the whale; whale stock of the seaboard went down, and lard oil stock of the west went up, and the cornfields had a wider margin. Camphene and fluid, soon after lard oil had, as it was supposed, become the great *light*, yielded to their more brilliant display, and the greasy product of pork again found its level.

But as corn was directly appealed to for *light*, it was a matter of indifference to the

western farmer whether it was supplied directly from corn or its product, pork, so long as he held the monopoly of its production. But genius and Yankee perseverance did not stop here; and the coal mines were explored for more light, and they had just begun to yield it in the shape of kerosene, when the discovery of the oil wells burst upon the wondering west. Camphene, fluid and kerosene from coal were at once extinguished by the floods from the oil wells, and corn that had become the great staple not only for food, but light, had to give place in turn to the new power.

While *genius* was busy carving out a fortune for this new product, she was not unmindful of the great staple corn, and by new modes of culture and new implements so cheapened its cost that it retained an important place in commercial circles. Of late, in consequence of forcing a double amount of freight on the northern transportation lines, the price of this staple at the west has gone down below the cost of production, while at the seaboard it commands a pretty fair price. Should this state of things continue, corn will cease to be named among the agricultural staples arriving at tide-water from the west. The present price of corn at New York is sixty-two cents, and at Chicago twenty-two, showing a cost of forty cents for freight, at least double the ordinary rates. The average cost of placing corn in the Chicago market from the country stations is nine cents, that is, eight cents for freight, and one cent for selling. The buyer must have three cents for buying, shelling and shipping at the station, which leaves to the farmer just ten cents a bushel, only one-half of its nett cost of production, after allowing a fair price for the use of land, fixtures, etc. Now it is nonsense to suppose that farmers will continue to grow corn any great length of time at this rate; in fact but few farmers would have the ability to do it, even if they chose to make the attempt. The re-opening of the southern trade, or the re-opening of the Baltimore and Ohio railroad, with increased competition among the northern transportation lines must, at no distant day, bring down these enormous freights to a reasonable standard. It will be seen that a reduction of twenty-five per cent. will have the effect to keep up the supply, but if reduced to twenty cents a bushel, would leave a handsome profit to the western farmer. The ordinary lake freight is five cents a bushel to Buffalo, but last fall it was up to fifteen on an average; all we need ask to leave us the monopoly of corn is the reduction of the extra lake freight. We can see no reason why corn cannot be laid down in New York at less than the present price, and yet pay all parties a fair profit. With twenty-five cents at the country stations for shelled corn, the western farmer would be well satisfied, as that would leave him a round profit; the average freight to Chicago, eight cents, re-shipping, two

cents; to Buffalo, five cents, re-shipping, one cent; to New York, thirteen cents; insurance one cent—total fifty-five cents. As some one must be paid for advancing the money and looking after the shipment and sales we add for that purpose five cents a bushel, a sum ample in all respects. This will make the entire cost at which corn should be laid down in New York sixty cents a bushel of fifty-six pounds. With these facts before him the eastern farmer will know whether or not he can compete with the west in this staple, and meet his brother farmers of the prairie on change in the seaboard cities.

It is generally supposed that the whole of the State of Illinois is a great corn producing country, but such is not the fact. The northern counties seldom produce a surplus over the local demand, being more occupied with the culture of spring wheat and the products of the dairy. The south half of the State as often purchases as sells, and it is the central portion that produces the immense supply that has made the State famous for this great staple. The south part of the State is known as *Egypt*, and is valuable for the grape, the peach, and other fruits that require a long season and a hot sun. The climate corresponds with that of at least four degrees of latitude further south on the Atlantic slope, or equal to that of the Carolinas, north of Columbia, South Carolina, though from its inland position, subject to more sudden changes of weather. In the more southern portion of this section, the winter wheat harvest commences the 25th of May. It is therefore strictly within the cotton growing region, and extensive preparations are being made to try the effect of free labor with this crop. A large portion of the inhabitants are more or less familiar with its culture, and we have no doubt of its success. The great error with people settling in that part of the State, has been their ignoring the idea of the low summer latitude, that is so marked a feature in the climate. The general elevation of the country is three to six hundred feet above the level of the sea, and on the whole possessing a climate soft and delicious as that of Italy. This part of the State has never been appreciated, because not understood, but now the war, by stimulating the growth of cotton, of tobacco, and of sugar, in the more northern portions of the region adapted to them, will people that part of the State with an industrious and enterprising population.

The lands are among the richest, and as they can be purchased at a low price, we shall expect to see immigration directed to that interesting part of the west. The Germans of Western Texas have proved that cotton can be profitably cultivated with free labor. With these facts before us, we need have no misgivings of the result, when backed with northern industry, northern skill, and northern implements on the rich soil of the basin of *Egypt*.

Messrs. Editors, would you like a trip to the west—to visit the gardens of Chicago just as the cherry tree is sheeted with its mantle of white—pass south through the great corn zone, and feast your eyes on far stretching fields of thousands of acres of the springing blades—away down the prairie slopes into the basin of Egypt—drive among the fruit hills of the “Grand Chain,” amid orchards laden with the young fruit and fields of wheat nearly ready for the harvest, and with the forest full-robed for summer? Come, and we will show you the prairie state in its vesture of vernal flora and midsummer splendor, *all in May*. It will be no tiresome ride over plains, across which the iron rail had just been laid, with the cabin of the emigrant or an impromptu village to relieve the grey setting of the prairie, and over which the autumn fires had gathered up the gifts of summer. It will show you the difference between then and now, and between the more exacting climate of the Lake region and the genial skies of the Valley of the Mississippi—between the semi-tropical products of the thirty-seventh parallel, and the hardy cereals of the north at forty-two.

M. L. DUNLAP.

—Country Gentleman.

### The Composition, &c., of Milk.

(Concluded from page 209.)

#### METHODS OF TESTING MILK.

It has been at various times suggested to me to consider whether a really method of testing the quality of milk might not be devised. It is true that we have instruments—lactometers, as they are called—for ascertaining what is the quality of milk. But the instruments in use lead frequently to erroneous conclusions: they were based—most of them, at least, on erroneous principles. The common lactometer, which is in effect a float, like an ordinary spirit-float, when immersed in milk, indicates by its position the strength of that liquid. Milk which is more dense keeps the float higher: milk which is less dense allows it to sink lower. When water, therefore, is mixed with milk, the float will sink deeper. So it is said by those who constructed this description of lactometer. But there is one consideration which has here to be taken into account. It is this—that the butter in the cream is lighter than the whey of milk. Cream, I find by direct determinations, has a specific gravity of 1.012 to 1.019. It varies slightly. It is a little heavier than water, but lighter than the whey of milk, or skimmed

milk. Milk rich in cream would, therefore, be lighter than milk poor in cream. By this lactometer an extra quantity of cream in milk is indicated in precisely the same way as an extra quantity of water. In short, this instrument, which measures the density of milk, furnishes very incorrect results. I cannot, perhaps, make this clearer to you than by giving one or two determinations. In testing the specific gravity of good milk, I found it as follows: 1.03 to 1.032. By skimming off the cream the gravity is increased. The lactometer, again immersed in the skimmed milk, now rises five divisions, and indicates 1.037. But if I take off from this milk the cream, and then put 10 per cent. of water to it, I get again precisely the same specific gravity which the new milk originally indicated, namely, 1.032. I believe that the commonest adulteration practised in large towns consists in people taking off the cream, and then if the milk be particularly good, adding a little water. This is not indicated by the common lactometer. Indeed, this was pointed out some time ago, and persons have in consequence sought to construct a lactometer on totally different principles. If the milk is put in a graduated glass and allowed to settle, some of the cream rises, and the quantity can then be read off. In good milk I find from 10 to 12 per cent. of cream by volume; in poor milk there is sometimes as little as from 6 to 7 per cent. of cream. Although this instrument (holding it up) does not give absolutely accurate results, yet it gives more useful results than I was first led to believe it would. It also gives results which are comparable. There are a number of tubes to compare the cream-producing qualities of milk; and these might easily be put together in one piece of apparatus in a rack or box. I have here a case which may, if necessary, be filled with cold water. The tubes are graduated from the top, indicating the amount of cream which collects after the milk has been for some time standing. Temperature has, as is well known, an influence on the separation of the cream, but not so great an influence, as I find by experiments, as is generally believed. When the temperature is about 50 degrees, most of the cream is separated from the milk in from 18 to 24 hours. A small quantity only remains in the skimmed milk; about 7-10ths of a per cent. of fatty matter remains in it. However long you may keep milk at rest, it is impossible to separate the cream completely, but the greater portion separates in about 24 hours, and if the process be conducted at a temperature of about 50 degrees longer time than 24 hours will not separate an appreciably larger quantity of butter. I have kept milk in this instrument for 36 hours without getting a larger quantity of cream. This, however, is not quite conclusive, for the cream may get denser the longer it stands. It becomes denser when the temperature is increased; it diminishes slightly in quantity when the tempera-

ture is increased to 70 degrees; but under such circumstances the cream becomes denser. In comparative experiments like these, it is well to maintain as nearly as possible an equal temperature. It is also desirable to shut out the influence of the air. This may be done very well by means of a tin case in which 3 or more lactometers may be placed. The milk may be kept cold by cold water, and a thermometer inserted in the tin-case to indicate the temperature. [The lecturer here showed practically how this might be done.] In comparing these two methods with each other—the one which collects the amount of cream, and the one which gives the gravity or density of milk—it has struck me that a more correct result might be obtained if two instruments were used together; one to measure the amount of cream and the other to take the density of the skimmed milk. Milk skimmed and watered will give at once little cream, and show a low specific gravity; whereas, milk which was merely skimmed and not otherwise watered would give a higher specific gravity than milk in its natural condition, but would give little cream. People using both instruments would be in a position to say at once, "This milk is watered;" or, "It is otherwise good milk, but the cream has been removed." When large quantities of milk have to be supplied to work-houses or public institutions, it is very desirable to have a ready mode of testing its quality. It might be arranged that when the milk comes in, some of it should be placed in graduated tubes, and at the end of twenty-four hours, the skimmed milk could be drawn off, and a float put into it. This float might be so constructed as to give the proportion of water in the milk from 10 to 12 per cent. I purpose to make a number of analyses of milk purposely mixed with water, and to construct a set of two instruments with a view of assisting in the solution of this practical question, and testing in a ready way the quality of milk. I believe the thing can be done with some care and trouble. When the ordinary lactometer, which measures the amount of cream in the milk, is used, practical difficulty is experienced in removing the cream. You might do it with a pipette; but unless you have a very steady hand indeed you cannot get all the cream off: at any rate, the servants in a large establishment could not be expected to do it. I have, therefore thought of using an instrument similar to the alcalimeter of Dr. Moore, analytical chemist of Coblenz. It is a very handy instrument, which is frequently used for many purposes in chemical laboratories. It consists of a graduated tube divided into one hundred parts, each of seven grains, the whole being the hundredth part of a gallon. You will, by this means, get a proportionate part of a gallon. The milk is filled in, and then left-four and twenty hours. The cream rises, and can be

readily let off. [The Professor gave a practical illustration with the apparatus.] The whole operation is very simple. The specimen which I have here seems to be an exceedingly good milk, it contains no less than fifteen measures of cream. I put the sample here that I might be able clearly to exhibit the process. It is rarely that you get such a large amount of cream. If in London milk you get eight or nine measures of cream, you must be satisfied: very frequently you will get only seven, and even six measures. You can see distinctly [referring to the graduated tube] the line which separates the cream from the skimmed milk. The milk is prevented from flowing out by a list of India rubber tubing, which is pressed together by a kind of clasp, which opens the tube on applying pressure to it. By this means the skimmed milk may be drawn off with the greatest ease. After that a float is used to ascertain the specific gravity. The instrument which gives the specific gravity might be so constructed as at once to indicate ten, twenty, forty, or fifty per cent. of water in the milk. By means of this arrangement you get an idea of the quality of the skimmed milk, and are able to ascertain whether or not it is poor and thin; and you also measure off the quantity of cream. I am at present endeavouring to ascertain whether the cream is of anything like uniform composition when gathered in this way. If it be so, we might thus form an idea of the amount of butter which can be produced by a given quantity of milk; and in large dairy establishments which cannot be superintended by the owner, very great services might, I think, be rendered by enabling him to ascertain at once what amount of butter he might fairly expect from his dairywoman. There is another description of lactometer, or milk-tester, as it is called, which is simply a graduated cylinder, by which the milk is kept from the influence of the atmosphere, and which in other respects resembles these graduated tubes. In all ordinary tubes in which the graduation begins at the top there is this practical inconvenience, that the skimmed milk cannot be removed by such a simple arrangement as that which I have described. I have lately directed my attention to the construction of a good milk-tester. There are various things to be taken into account, which I am engaged in investigating. For instance, I am endeavouring to ascertain whether the quantity of cream which is thrown off in a small-bore tube is larger or smaller than that thrown off in a large-bore tube—whether, in fact, size makes any appreciable difference in the volume. So far as I have gone I have not found any great difference in the volume of cream which is thrown up in graduated tubes of different diameter. Thus far, the indications are favourable; and I hope, at no very remote period, with the assistance of Mr. Griffin, the manufacturer of chemical apparatus, to produce a practically useful set

of lactometers. With these remarks on milk-testing I will conclude this lecture, and thank you for your kind attention. (Cheers.)

Mr. Beale Brown said he felt great pleasure in moving a vote of thanks to Professor Voelcker for the able and interesting lecture which he had just delivered. Perhaps the most interesting portion of the lecture was that in which it was shown that an increase in the quantity of food did not necessarily lead to an increase in the quantity of milk. He had found by his own experience that it was possible to give additional food to his cows, which tended to fatten them, without making any difference in the quantity of cream. He wished to ask the Professor one or two questions, and he should feel obliged by his answering them. He said it was impossible to separate all the cream from the skimmed milk. Would he state whether the practice of scalding milk, which was practised in Devonshire, did not produce a complete separation? He wished, also, to enquire what, in the Professor's opinion, was the effect of gorse on milking-cows. In the *Irish Farmers' Gazette* it was stated that the use of gorse greatly increased the quantity of milk; and if that were so, it might be well to resort to gorse at a period of the year when other kinds of food were not abundant.

Professor Voelcker said, as regarded gorse, although he had made an analysis of it, he was not practically acquainted with its influence upon dairy stock. From what he knew, however, of its composition, and of its practical effect in the case of horses, he was inclined to think that it might be given with great advantage to dairy stock. In some parts of Scotland, waste lands which did not bear anything before are now cultivated entirely with gorse, intended for horses; and he was inclined to think that a food which was given usefully to horses, being a concentrated food, might also be given with advantage to dairy stock. With regard to the other question, he had no doubt that the scalding of milk would throw up a little more cream; but no amount of boiling would effect a complete separation. Even in the clearest whey, when the curd was separated from the milk there remained a certain amount of cream suspended.

Lord Feversham, in seconding the vote of thanks, said, although the Professor's treatment of it was important, there were some interesting parts of the question into which he had not entered, and upon which information might naturally be desired. As regarded the analyses and experiments which had been mentioned, he must remark that, unless comparisons were made between animals of the same kind, it was very difficult to draw satisfactory conclusions. They all knew that the Alderney cow gave much less milk than the Shorthorn, but that, at the same time, the milk yielded a great deal more cream and butter. They had not heard anything on that occasion with regard to the Devon and Hereford breeds.

The Chairman observed that Professor Voelcker stated distinctly that his comparison was between three Shorthorns and three ordinary dairy cows.

Lord Feversham continued: there could be no doubt that grass-fed cows would in summer yield an abundance of milk if the pastures were good, and that the butter would generally be of good quality. As regarded winter keep, they might, no doubt, easily feed cows with too much oil-cake, and so injure their milking properties and diminish the quality of cream; but he supposed the Professor did not object to their being fed on roots, mangold wurzel, or Swede turnips. Turnips might sometimes impart a taste to the milk, and therefore to the butter; but he (Lord Feversham) certainly considered mangold wurzel early in the spring an important and essential element in the feeding of milch cows. That root would not generate too much fat in the animal, and it would, he believed, rather increase the quantity of milk. The noble lord concluded by expressing a hope that the lecture would at once go forth to the agricultural public generally.

The Chairman remarked, that some years ago the subject of the composition of the milk of dairy cows was before under discussion. A great desire was then expressed for some means of securing the cream without the process of skimming; and it was suggested that that might be done by means of a syphon.

Mr. Moore thought he gathered from Professor Voelcker that the three Shorthorns and the three dairy cows of which he spoke were kept out at grass during the analyses.

Professor Voelcker said both sets of cows were out at grass, and remained under the same circumstances during the experiments.

Mr. Moore; The result of giving cake to both classes of animals was, that it lessened the quantity of milk yielded by both.

Professor Voelcker: Exactly so.

Mr. Moore thought he also gathered from the lecturer that the size of the vessel in which the milk was placed, whether it was large or small, did not increase or lessen the quantity of cream. Some years ago considerable discussion took place as to what should be the shape and size of milk-pans. He should like to know whether the Professor thought that any particular shape, or any particular depth of pan, would affect the quantity of cream which a given amount of milk would yield. Some years ago he (Mr. Moore) made some experiments with respect to the produce of Alderney cows, Shorthorns and Herefords, and the results were very satisfactory. He tested the milk in various ways, using a syphon, referring to the dates from the time of calving, and so on, and he found the quantity of milk in the case of these different breeds of animals very uniform, although there was a considerable difference in quality.

Professor Voelcker, in reply, said the question with regard to the proper depth of milk pan was answered by the experience of good dairymen. They found that shallow pans were the best; such pans threw up more cream than the others, and kept the quality of the milk better. The temperature was better regulated, which was very important, because when milk became heated it soon spoilt. It was quite an erroneous supposition that the access of air was injurious. The freer current of air there was through a dairy the better. What was injurious to milk was damp air. He was glad to see in the room a gentleman from Sweden, Professor Muller, who could, if he pleased, give them some interesting information with respect to the mode of keeping milk in that country. In a little book, published by a gentlemen in Sweden, there was a plan mentioned which consisted simply of keeping milk in shallow vessels of peculiar shape and handy construction, and admitting the air freely to it; at the same time you might make a fire in the dairy whenever one was required; and the author stated that whenever he saw a thunder storm approaching, instead of keeping his milk cool, he had a fire lighted to drive off the additional moisture.

Mr. Cantrell said the kind of pan which he had found best was a common earthenware pan, with a yellow glazed lining inside.

Professor Voelcker remarked that the great point was to have a shallow pan, with a perfectly smooth surface.

Mr. Blackburn said that he had always found that a small depth of pan threw up the largest quantity of cream, especially in warm weather. Milk would not keep so long in warm weather as in cold; and the sooner, therefore, the cream was thrown up, the better. In summer he invariably adhered to a pan of 1½ inches in depth and in winter to one of 4 inches. On that plan, the cream was thrown up much quicker, and the skimmed milk did not remain sufficiently long to acquire acidity. He had found that bean-meal produced a greater quantity of milk than any other kind of food. He had used it largely: and on comparing its effects with those of rape-cake and linseed-cake, he had found that it contained a larger amount of flesh-making principles than those substances, and not so much oil. He should like to learn why there was such milk-producing power in bean-meal.

Professor Voelcker said it contained a considerable quantity of starch. It was a fact borne out by experience, that bean-meal produced a large quantity of butter.

Mr. Blackburn said another substance which he had found to produce a large quantity of milk was grains, or draft. He supposed that it contained a large quantity of phosphoric acid.

Professor Voelcker: Yes, and lactic acid. It contained a large quantity of phosphate of lime, which was held in solution. A certain amount

of grains was exceedingly useful for dairy stock, and so also was bran.

Mr. Blackburn said he had fed largely with bran. There was great difference between linseed and rape-cake. Linseed gave a very unpleasant smell; whereas rape-cake was more like grass land in its effects. The explanation might perhaps be, that the oil in rape-cake more resembled the oil in butter than the oil of linseed-cake resembled it. As regarded lactometers, he had used them for several years, and had encountered the difficulties to which the Professor had alluded. He would ask him whether some plan had not been devised for ascertaining the opacity of milk, or rather, the resistance which a column of milk offered to the passage of a ray of light, and measuring it? Was not that a good test?

Professor Voelcker observed that there was such a lactometer; and it was altogether erroneous in principle.

Mr. Blackburn observed that milk was very much injured by travelling a long distance, the cream being so diffused in the milk, that it would not rise.

Professor Voelcker could easily understand that. The milk globules were quite broken in travelling; their contents were diffused through the whole mass, and consequently it was more difficult for the cream to rise.

Mr. Blackburn considered the keeping milk cool a very important point. He had to send a large quantity of milk twenty-five miles by railway, and if it arrived in a coagulated state it would be unfit for consumption. Formerly it was his practice to have the milk placed in the pans just as it came from the cows, at a temperature of about 60 degrees, and he had frequent complaints of the quality of the milk. He then made several experiments, with a view to improvement. Eventually he tried the plan of putting milk in refrigerators, and bringing down the temperature to that of water. The plan entirely succeeded; and since its adoption he had not had a single complaint. It was exceedingly important that milk should be kept as quiet as possible, and should be placed in pans, for transmission, before it was quite cool.

### On the Composition and Feeding Value of the Straws of the Cereals.

BY THOMAS ANDERSON, M.D., F.R.S.E.

Nothing is more striking than the increased importance which straw has acquired in the modern practice of agriculture as a food for fattening cattle. Under the old system it was employed almost entirely as fodder, and when it was occasionally added to turnips, it was given less with the idea of any advantage to be derived from the nutritive matters it contained than with the view of correcting the too watery

character of that root, and thus facilitating rumination, promoting digestion and rendering it more valuable. In many parts of the country the property of using it in this way even was questioned, and it was never resorted to except in times of scarcity, when other and more nutritive food could not be obtained. Nor is this opinion at all surprising. We are in the habit of considering the moisture and more succulent varieties of food as the most nutritive, and with them the dry and woody straws contrast unfavourably; but they do so not so much on account of the absence of nutritive matters as on their less valuable condition, due to the large amount of woody fibre by which they are protected from the action of the gastric juice, and enabled to pass through the animal in an undigested state. Hence it is that straw, when used alone, must be described as comparatively an in-nutritious food, and was naturally and justly considered to be inferior to hay, which, in the last century and the earlier part of this, was the staple food of fattening cattle. At that time the amount of the hay crop was in fact, the measure of the number of cattle which could be fattened on any farm; but the turnip immediately increased this number, and as its cultivation could be extended more than the hay crop, and the increasing price of meat added to the profits, it was pushed to the extreme, and it then became necessary to use straw to mix with the watery roots. As the advantages of this course became obvious, both in the increased quantity of fat stock, which could be sold off the farm, and the abundance of manure it afforded for the other crops, every inducement was offered to persevere in it, and the consumption of purchased food commenced and rapidly advanced. As most of these foods are of foreign growth, it was, of course, profitable to import only those which contain abundance of nutriment within a small weight, and hence again straw became necessary for the purpose of adding to the bulk of these substances, and enabling the stomach to dispose of them in a more satisfactory manner than it would otherwise do; for a very concentrated food which does not sufficiently distend that organ may pass through the intestines to a great extent undigested.

Such is the history of the use of straw in fattening cattle, and with its extension many questions of interest have arisen. It is now admitted that its nutritive effect is much higher than was formerly supposed, but we are still without any definite information as to its value compared with other feeding substances, such as turnips and the like; and further, as to whether there is any and what, difference between the straws of the different grains and of the same grain grown under different circumstances. It is generally understood that oat straw is superior to either barley or wheat, and it is also believed that the soil and other circumstances have a very important influence upon their feeding

qualities, while it is also possible that there may be an appreciable difference in the straw of different varieties of the same grain. It is sufficiently obvious that a complete reply to all these questions would involve the analysis of many hundred specimens of straw, extending over a considerable period, so as to eliminate the effect of season, which in a single year is very apt to mislead. Still in the present imperfect state of our information a more limited inquiry will be of use; and it is hoped that the following investigation may prove an acceptable addition to our knowledge of this important subject.

In carrying out this inquiry it was of primary importance to devise some method of analysis suited to bring out the differences I wished to detect, and for this purpose the ordinary methods employed with oil-cakes, the cereals, &c., and which answer perfectly well for these concentrated substances, are of comparatively little use. They are founded upon the principle of determining the total amount of the different great classes or sections into which the nutritive elements of plants are divided. Thus, for example, in wheat we determine the amount of albuminous compounds, as measured by the nitrogen, of respiratory principles, and of oil, and in this case, when each group actually consists almost entirely of one substance, the information so obtained is amply sufficient. Thus, in wheat the albuminous matters consist almost entirely of gluten, and, the respiratory of starch, and the whole grain is easily digestible. But it is quite otherwise with a straw, where our object is not only to discover what substances are there, but also what proportion of them is likely to be available to the animal and to be assimilated by it in the process of digestion. It then becomes necessary to separate from one another the assimilable and non-assimilable substances, and this touches upon one of those points in chemical analysis which are in an unsatisfactory and imperfect state, and which require and merit further study. I commenced, therefore, by directing my attention to these points, and bestowed upon them a large amount of time, and performed a number of experiments, the results of which it is unnecessary to detail here. The general conclusion to which I came was, that though it might be possible to devise processes by which the proximate principles might be separated in some substances, it would not be practicable in all. Moreover, it did not appear that the separation of each of these compounds would throw any clear light upon their relative digestibility, and that, in the present state of our knowledge, it would be better, as well as safer, to restrict ourselves to a more limited analysis, though still more complete than those usually made.

It is obvious that if a food contains a considerable quantity of any nutritive element, as albumen, for example, but from some peculiarity in the condition in which it is present only a por-

tion, say a half or a third, can be assimilated, the value of the food is to be measured by that portion only, and not by the whole. The more nutritive foods are valuable not merely on account of the large proportion of useful substances they contain, but also because they are easily accessible to the animal. Thus in the turnip by far the greater part of its nutritive matters is soluble in water, little more than 2 per cent. of its weight being insoluble in that fluid, and of this small quantity a considerable proportion is dissolved by the juices of the stomach. In the cereals, although but a small proportion is directly soluble in water, the chemical changes they undergo during digestion convert them easily into a condition in which they can be absorbed. But it is quite otherwise with straws. In them the chief nutritive matters are partly soluble and partly insoluble in water, and they contain besides a large proportion of inert woody fibre. It will be easily understood that the substances soluble in water will be readily assimilated by the animal; and even those which are insoluble might, and probably would, also be taken up if it were not for the woody fibre which surrounds and protects them, and if it does not altogether prevent, must certainly greatly diminish the chances of their utility. Even in the most valuable food but a small proportion of the nutritive matters present is assimilated, and does not admit of a doubt that the portion soluble in water, or that which is most readily converted into a soluble state, will alone be absorbed.

In straws, it may be fairly anticipated that the soluble part is likely to be of use, and that the other portion, though it may, if rendered soluble, become useful, is so thoroughly protected from the action of the gastric juice by the woody fibre in which it is enveloped that in all probability it generally, if not invariably, escapes assimilation. In consideration of these facts it appeared to me that all the necessary requirements would be fulfilled by determining separately the quantities of each group of nutritive elements contained in the straws which are soluble and insoluble in water.

In following out this view of the matter, I at first attempted to effect the separation by macerating the straw in cold water, but it was soon found that in this way only a small quantity of soluble matters could be obtained, unless they were left in contact for a long time, and then a species of fermentation was apt to occur, which entirely altered the straw, and defeated the object in view. On the other hand, boiling water was inapplicable, owing to its producing coagulation of some of the albuminous compounds. After some trials a temperature of 140 degs. Fahrenheit was adopted, and was found sufficiently high to ensure the extraction of all soluble matters, without running the risk of rendering any of the albuminous compounds insoluble. The first

fluid obtained in this way, by adding to the straw about ten times its weight of water, was brownish coloured and slightly mucilaginous, and contained the greater part of the soluble matters. Three or four subsequent additions of water were found sufficient for their complete extraction. The total amount of soluble and insoluble matters was thus determined, and the proportions of soluble and insoluble albuminous compounds were ascertained by determining the total nitrogen and the amount left in the insoluble matter. Owing to the bulky nature of straw, and the small proportion of nitrogen, this required very great care, and duplicate experiments were made, with closely corresponding results.

*Wheat Straw.*—Samples of wheat straw, of good ordinary quality from East Lothian and from the neighbourhood of Midhurst in Kent have been examined.

In examining these analyses, it is impossible to fail being struck by the small proportion of matters soluble in water which wheat straw contains. Excluding the ash, they amount in the first sample to no more than  $3\frac{1}{2}$  per cent., and in the other two to 7 and  $6\frac{1}{2}$  per cent. respectively. To these the large portion of soluble ash forms a very remarkable contrast, in two of the samples greatly exceeding the insoluble ash, and in the third (that from Camptown), though it falls short of the insoluble part, it must still be looked upon as proportionately large. The largest individual constituent in all these straws is the insoluble respiratory elements, and they materially exceed the woody fibre in quantity, a result for which I was not prepared. It is interesting to notice that, if we take the total albuminous and respiratory compounds, the difference between the specimens is by no means large, and the two East Lothian straws in particular are almost absolutely identical. It is only when the relative quantities of soluble and insoluble matters are taken into account that the difference becomes apparent.

*Barley Straw.*—Samples of barley straw were obtained from the same localities as the wheat

straw, and are here distinguished as numbers 1<sup>st</sup>, 2, and 3 :—

| Soluble in Water—      | No. 1. | No. 2. | No. 3. |
|------------------------|--------|--------|--------|
| Respiratory elements   | 3.22   | 6.11   | 4.56   |
| *Albuminous compounds  | 1.42   | 0.39   | 0.66   |
| Ash                    | 3.30   | 2.87   | 3.38   |
| Insoluble in Water—    |        |        |        |
| Oil                    | 0.97   | 0.88   | 1.05   |
| Respiratory elements   | 35.56  | 38.39  | 27.95  |
| †Albuminous compounds  | 1.54   | 1.12   | 1.98   |
| Woody fibre            | 41.34  | 36.62  | 47.53  |
| Ash                    | 0.91   | 2.75   | 1.47   |
| Water                  | 11.41  | 11.15  | 11.10  |
|                        | 99.70  | 100.27 | 99.68  |
| *Containing nitrogen   | 0.228  | 0.063  | 0.106  |
| † " nitrogen           | 0.217  | 0.180  | 0.317  |
| Total nitrogen         | 0.475  | 0.243  | 0.423  |
| " albuminous compounds | 2.960  | 1.510  | 2.640  |
| " respiratory elements | 38.780 | 44.490 | 32.510 |

In these samples the differences are far from inconsiderable. In the first the total percentage of albuminous compounds is about twice as great as in the other two, and it is nearly equally divided between the soluble and insoluble. In both the others the proportion of insoluble albuminous compounds exceeds materially the soluble. The total quantity is also larger than in any of the wheat straws, and there is likewise a considerable difference in the amount of respiratory elements and fibre, the latter varying from little more than one-third of the entire weight of the straw, in No. 2, to nearly a half in No. 3. It cannot be doubted that these differences must tell on the nutritive value of the samples, and that the first would, under ordinary circumstances, prove the most valuable, and the third the least so.

*Oat Straw.*—Owing to the great importance of oat straw, and its generally admitted superiority as a feeding substance, a larger number of analyses have been made of it than of the other grains.

These analyses fully justify the preference accorded to oat straw in feeding, for all of them show a larger and most of them a much larger proportion of soluble matters than either wheat or barley. There is however, a very great difference between the samples; that from Millhill containing nearly twice as much soluble as some of the others. If this be taken as a measure of their relative values, then we should be induced to place that sample, and the sandy oat straw from Mr. Skirving, on a considerably higher level than any of the others; while that from Kent would stand lowest. And this conclusion is justified by practical observation. In fact, the specimen from Kent was sent me by Lord Kin

naired, for the purpose of ascertaining whether there was any difference in the consumption of it and of the straw grown on his home farm at Millhill, because he had found a very material difference in their feeding properties. The straws grown on the sea level, and at 850 feet above it were analysed for a similar reason; it having been stated by Mr. Harvey, of Whittingham Mains, that there is believed to be a difference in their feeding qualities. The analyses scarcely bear out this opinion, as far at least as these two samples are concerned; for though that from the high level is slightly superior to the other, the difference is so small that no conclusions can be drawn from it; indeed, specimens from different localities vary to a much greater extent.

Passing from these points to the more general considerations regarding the nutritive properties of straw, it must be observed that their value is much higher than might have been expected. The position in which they stand may be best rendered obvious by a comparison with the turnip. That root contains on the average from 1.2 to 1.4 per cent. of albuminous compounds, and 4 or 5 of respiratory elements, of which 3 or 4 are soluble in water. It will be observed, then, that, as far as nutritive matters are concerned, straws generally stand far above the turnip, surpassing it slightly in the albuminous, and enormously in the respiratory elements. As a source of these elements they must hold a very high position, and in this respect are surpassed only by the grains and some few other substances. When compared with roots and grains, however, a very marked difference may be observed between the relative proportions of these two great classes of nutritive elements. The ratio of the albuminous to the respiratory compounds is, in the turnip, as 1 to 3. In round numbers, and in the grains as 1 to 7. That is to say, for every pound of the albuminous compounds contained in a grain, as wheat for example, there will be about 7 pounds of respiratory compounds. In the straws, the proportions are very different, the total respiratory compounds being never less than ten, and sometimes nearly thirty times as abundant as the albuminous. If the soluble portion of these substances only be considered, then the ratio approaches nearer to that observed in the more concentrated foods, though on the whole the excess of respiratory elements is very marked.

Returning now to the comparison between the turnip and straws, it is obvious that though the latter greatly exceed the former in the amount of substances which may be absorbed, no one would for a moment think of asserting that straws are therefore of greater nutritive value. The reverse is undoubtedly the case, and the cause of this is to be found in several considerations. 1st. It must be attributed in part to the unsuitable proportion of those classes of nutri-

tive substances; for if highly nutritive substances, such as the turnip and grains, contain a relatively much larger proportion of albuminous compounds, then it may be expected that in the straw the small quantity of these substances will cause the assimilation of only a proportionate quantity of the respiratory elements, and the surplus will be waste. Hence also the use of highly nitrogenous foods, such as oil-cake and bean-meal, along with straw, must be considered good practice. 3rd. It may be fairly anticipated that the soluble portion of the nutritive matter will in general be of little, or possibly sometimes of no use. 2nd. Owing to the difficulty with which the soluble matters pass into solution in water, a considerable part of them may escape digestion. And in this respect the contrast between straw and turnip is very marked. In the latter the larger proportion of the constituents are not only soluble, but already dissolved in the 90 per cent. of water present, but in the former they are not dissolved, but are in the solid state in the dry straw, and must undergo the process of solution, which is effected during mastication and rumination. The difficulty of dissolving the soluble matters of straw in cold water has been already adverted to, and even when warm water is used the process is slow, and requires considerable time. From this it may be concluded that straw ought to be well moistened and steamed before being used. 4th. The large proportion of woody fibre existing in all straws must interfere materially with the production of the full effect of its nutritive elements.

Notwithstanding these drawbacks, the general conclusion to be drawn from this inquiry is, that straw, and more especially oat straw, possesses a very considerable nutritive value, but that it is most advantageously used along with the more highly nitrogenised foods. It must be observed, also, that in a mechanical point of view, it may even have its uses in the intestines, and by giving bulk and firmness to the mass of food contained in them, assist the process of digestion and absorption. Such are the conclusions to which analysis leads; and I will only add, that a minute and careful series of feeding experiments with straw, under different circumstances, would be a great boon to practical agriculture.—*Transactions of Highland Society.*

### The Farmer as an Observer.

It has long seemed to the writer that the greatest defect in agricultural literature, as in all other, is the want of originality. As said a gentleman of the Empire State, several years ago to the writer, "we have had what is known up over again and again by editors and contributors to papers, who have done nothing really to advance the art of farming and stock-breeding. What we most want is men who by experiments

accurately made and reported shall advance the knowledge of tillage beyond where it has stood for many years." There is still the same deplorable lack of originality in the literature of the farmer.

The query at once presents itself, how is this to be done? Not by reading the records of the past alone, however valuable they are, but by observing with critical care all the phenomena connected with vegetable and animal physiology, in relation both to the earth and the atmosphere, including everything that affects the condition of domesticated animals and cultivated plants. Books contained only the known, and so far as their contents are valuable and useful they report the exact processes of nature in regard to the subjects discussed. Let the reader learn to discriminate therefore between knowledge and theory; in doing so he will soon learn that there is a wide difference between knowledge and theory, between experiment and hypothesis, between fine talking and writing and working in the field, between actual observation and predictable assertion.

In christianity faith is a fundamental, and therefore an indispensable element. But in physics demonstration entirely precludes the necessity of faith, and therefore the reader of an agricultural paper desires, and especially so if he is a practical farmer, to learn what a man knows, not what he believes, or what he asserts from hearsay. Neither by many or by few words does a writer commend himself is what they desire, whether it be conveyed in many or to the real hungerers and thirsters for knowledge. Truth, few words. Some pride themselves on short articles, seeming to convey the impression or conceit that because they write short articles, *ergo*, they are good; also that long articles, because they are long are worthless. Such, however, is not the decision of the analytical reader, for he learns to judge of the contents of a paper not by the length of its articles, but by their quality. What a man knows, not what he believes or has heard, is what the farmer wants and seeks by reading.

The advancement of farm literature must depend upon the observations of practical farmers, and not upon the hypothetical speculations of mere theorists, writers or lecturers who know nothing practically concerning the subjects they write or talk about.

What would a city schoolmaster say of a farmer who never taught school a day in his life, who should write an essay on school keeping, dictating how a school should be organized and conducted? Away with such nonsensical speculations, would say the practical teacher. Before undertaking to teach others, first learn by experience in the schoolroom what cannot be learned anywhere else; then instruct the masters. In such a decision the teacher would be right.

But to reverse the picture. Suppose a city schoolmaster, known as the principal of a select school for young ladies, should attempt to write or compile an essay or manual on practical farming. What would the farmers be likely to say of it? They would say, just what practical schoolmasters would say, of those who know nothing practically about school-keeping, yet attempt to dictate by lectures or essays how to conduct a school. Just for a moment contemplate a city schoolmaster attempting to instruct practical farmers on the rotation of crops. *Nesutor ultra crepidam*, is a Roman maxim of general application and at once suggests itself. It is quite as absurd for a schoolmaster to teach the practical farmer the niceties of the art of conducting a farm, or of economical agriculture, as it is for the farmer to attempt to teach the practical schoolmaster the art of conducting a school.

Did Mr. Bakewell, an Englishman, and the prince of stock-breeders learn his art from a schoolmaster's manual on farming? Did the Messrs. Colling produce the improved Short-horns in a similar way? Or was it not rather by observation and experience united. They were careful observers and experimenters; and thus the Messrs. Colling and Mr. Bakewell produced results that have proved their claim to the noble honor of being benefactors of mankind. They did something to advance the practical art of cattle and sheep breeding. Men of like spirit and enterprise are now wanted in every other department of farming.

He who by experimenting learns how to grow the greatest amount of wheat, rye, corn, barley or oats per acre, with the least cost per bushel, will then be able to teach what every farmer wishes to know and what no farmer now does know. He also in the same way teaches how to grow annually that crop which is most profitable without regard to rotation of crops, by application of suitable fertilizers, will be entitled to a place on the scroll of fame, by the side of Bakewell and Colling, as a benefactor of his race.

To the same honor he will be entitled who teaches the cheapest method of making beef, mutton, pork and wool—any or all of these staple products. These lessons can only be learned by experimenters in the field and in the garden, among herds and flocks, and in breeding and feeding. Facts thus developed will furnish the material for making the science of agriculture, when they are all known. The facts in the possession of practical farmers to day, that have never found their way into any book or paper, are worth infinitely more to practical and economical farmers, than all that have ever been printed, from the times of Cato and Columella, down to the present time.

Farmers! will you furnish facts for the *Country Gentleman*, no matter how common, for

they are needed and are worth infinitely more than speculations, no matter by whom produced. Too often is it the case when a farmer is invited to write for an agricultural paper, that he thinks he must produce a studied essay on some topic, when only *his facts* carefully presented with all their surroundings, are wanted. Farmers must learn to observe and record their observations, for in this way is agricultural literature to be advanced.

MENTOR.

—Country Gentleman.

### Pleuro-Pneumonia.

[We regret to hear that this fearful disease among cattle is again showing itself in the New England States. Recent accounts from Australia and even New Zealand, represent its ravages as most extensive and destructive. The following communication from an eminent Veterinarian first appeared in the *Fifeshire Journal*, and which we take from the *Irish Farmer's Gazette*. Eds.]

SIR,—Every communication I see in the newspapers from veterinarians about pleuro-pneumonia would lead agriculturists and the public generally to believe that infection was the whole cause of the disease.

I have seen as many cases of pleuro-pneumonia for the last nine years as I think could come under the notice of any veterinary practitioner, from young calves to old cows—in town byres, villages, farm steadings, and open fields, were its spontaneous origin has often been observed. If you were to tell a party who had reared all his own stock, and which had never been in contact with any other animal, that one of his was affected with pleuro he would scarcely believe you. When the disease became so prevalent in this part of the country, if an animal was observed to show the least symptom of it, it was at once put out of the way, and every precaution taken to prevent contagion; yet the disease went on. One farm I know of was scarcely ever without it till the courts were drained and all covered in, after which not another case occurred for four years, although about fifty head of cattle were kept on it. I know several farms, one in particular, where the steading is close by the road-side, and where they rear mostly all their own cattle; when calves they are always grazed at the road-side, and often on the road where cattle have travelled in the worst stages of disease, day after day, and disease raging on every side of it, yet there has never been a single case on that farm.

I know an extensive farmer who bought a short-horned bull, which he placed in a loose box along with a heifer. The bull shortly afterwards became affected with pleuro-pneumonia,

and died in the same place after fourteen days' illness. There was a door which communicated with other cattle, and on the opposite side a byre containing about twenty milch cows; but another case never occurred on that farm for three years. Another farmer told me that he bought eight cattle and kept them by themselves for a fortnight, and as they appeared healthy he then placed them in a park beside other fifty. Shortly afterwards, however, they became diseased, and were ultimately sold at a great sacrifice; but not one of the fifty ever became affected. I attended a yearling which belonged to a small drofter, and was affected with pleuro. It recovered, and was shortly afterwards sold in the market to a farmer whose stock I had occasion to visit, and in the midst of which I observed the same animal without any bad result. On many farms single cases occur without going farther. Now, if the disease is so infectious as some writers would have us believe, how is it so many beasts escaped when placed in such circumstances? I kept a cow for six months, during which she travelled to and from her pasture on the road leading to the railway station, where diseased cattle were repeatedly going, and other cows beside mine, without any bad effect. I know that on a farm where there are two byres, each containing ten polled cattle, four in each byre became affected with pleuro-pneumonia. They were all removed after showing symptoms of disease, and treated for recovery. All the eight recovered, and as they began to get better, they were returned to their own stalls, and in the summer the whole twenty were turned out to graze in the park, and none of the other twelve ever showed the least symptoms of the disease. I knew of other diseased cattle that were disposed of, and three healthy ones immediately put in their place without any bad effect, although they remained several months till they were fat.

These agriculturists that have suffered most from it are beginning to think that we must look for other causes than contagion—a conclusion to which I also have come; and instead of selling their lean stock when they become diseased for little more than the price of their skins, are now treating them for recovery, and in many cases very successfully. I may mention that I have had both valuable short-horned bulls and heifers badly affected with pleuro that recovered, and afterwards produced healthy stock.

The question is often asked of a veterinary surgeon, "What is the cause of pleuro-pneumonia?" In my opinion, the first cause has been the great demand for beef, and the way in which that beef has been reared to meet the demand. On many farms there are too many calves reared for the amount of accommodation, and their milk not always of genuine quality. The moment the calves are dropped from their dams

they are tied by the neck, and for months together allowed no more room than to lie down and rise up again, breathing all the time an atmosphere nearly up to suffocation point. Thus, being without pure air and exercise, neither their lungs nor any of their other organs are ever properly developed.

There are four things necessary for laying the foundation of a good constitution—viz., good shelter, proper food, pure air, and exercise. Without these combined, predisposition to disease is the result. The want of exercise to calves predisposes them to joint ill, white scour, quarter ill, and pleuro; and a great number fall victims to these diseases every year. Where great attention is paid to the rearing of stock, it is seldom—at least so far as my observation, goes—that there is anything wrong, in comparison to the opposite plan of rearing without exercise and cleanliness. I would say one of the great existing causes has been carried on since cattle travelled so much by steam-boat and railway. They are driven to markets and often placed in trucks in a heated state, frequently remaining there for a whole winter night, and, with lungs so predisposed, they catch cold, which soon generates into disease. Also, in the extreme heat of summer, when cattle run so much in the heat of the day, their lungs become congested; then we have cold nights, they lie down on the damp grass, and pleuro is often the result.

If Mr. Gamgee would put agriculturists on the proper mode of rearing cattle to prevent disease, he should recommend them to give good shelter, proper food, pure air, and exercise in winter, and provide a protection to them in grass parks from the extreme changes in summer, and to be better sheltered in railway trucks, with fewer delays. If that were done, we would have less disease; and the Edinburgh dairy-man would have cows with better constitutions, if they would give them better accommodation.—I am, &c.

COLIN C. BAIRD, V.S.

Cupar, Feb. 26th, 1842.

### Management of Live Stock in France.

(From the American Stock Journal)

We spoke in our last number, of the superior productiveness of English over French Agriculture in respect both to the crops, and to the animal product; and gave the estimate of Lavergne that the yearly animal product of an English farm is, upon an average, equal to the whole product of animals and crops upon a French farm of equal extent! The main secret of this strange fact is, that in the English system of husbandry, immense crops of turnips and green fodder are produced and fed out to sheep and cattle on the farm, thereby enriching the land and sustaining a heavy stock of animals for wool, mutton and beef. For instance, a Lincoln-

shire farmer thinks his farm under-stocked with sheep, if he does not feed on it, on the average, one sheep to each acre. His thousand-acre farm produces usually two hundred acres of turnips, and the like area of vetches, rye-grass and clover, all of which is consumed by his own animals, and so the land is enriched for his wheat and barley crops which he sells. The French farmer allows much of his land to lie fallow after a crop of wheat, instead of raising a green crop, and so he has nothing to feed to his animals, and can of course keep but few of them. It is, however, at this time our purpose to examine more in detail the French system of management of domestic animals, comparing it as we do with that of England, to see what lessons of warning or example Americans may find in this department of French husbandry.

#### CATTLE.

It is estimated that France possessed in 1855, about ten million head of horned cattle, while Great Britain and Ireland had about two millions less; yet is believed, upon the highest authority, that British agriculture on an area of land of less than three-fifths that of France produces one-fourth more meat, and twice as much milk for dairy products!

This is an astonishing difference, enough to attract the careful attention of all thoughtful men who are interested in agriculture. We will endeavor briefly to suggest the principal reasons for this result. Four different objects may be sought by keeping horned cattle,—meat, labour, milk and manure,—and as one or the other of these predominates in the mind of the farmer, so he will vary his treatment of his stock,

#### WORKING CATTLE.

In France, as in America, oxen are worked in the yoke. We have often seen them in the south of France yoked with a straight piece across their foreheads strapped to their horns, drawing by their heads, instead of by their shoulders as with us, and were surprised to see that they handled their load apparently quite as easily as in our fashion. Nowhere, however, in the world have we ever seen, nor can there anywhere else be found, so large and fine specimens of working oxen, as in New England. In England, cattle are, in general, not kept for work, but are bred for beef and milk only. There, an ox is a gentleman of leisure and dignity, fed with the fat of the land from calf-hood to maturity. A speedy growth and great weight are the main objects. His duty is to grow fat and heavy, to do no labour, to take no thought for the morrow what he shall eat; but to grow into butcher's meat as speedily as he may. He need not wander over a hundred-acre pasture, picking among stones in a summer drought for a scanty subsistence. Clover fields to his knees, or rye-grass brought to his stall, or five bushels of turnips a day, with oil-cake to match, are his inheritance, and he is bidden to rejoice in his youth,

for he will never see any old age. The breed of cattle that will make the most oeff at three years old on the most abundant feed, is best for the south and middle of England, and this is no doubt the Short Horn. As soon as he attains his growth, his career ends in the shambles; and a growing animal takes his place. Incidentally, of course, this enormous feeder furnishes an immense quantity of manure, and thus enriches the farm.

Now in France, as in New England, the first duty of an ox is to work. He may grow large and fat if he can, but he must work. In order to work he must be hardy and active, and of substantial age. Two-year-olds and even three-year-olds have no stamina; and so working oxen must be kept till seven or eight years old, and in fact, in all countries where they are worked, they are kept long after their growth ceases to pay their keeping. Cattle bred for labor are, no doubt, rendered more hardy by ranging in pastures, than being kept in small inclosures, and perhaps their meat is more healthful; but this free sort of life does not lay on fat like stall-feeding.

Is it profitable to work oxen? In France cows are worked often upon the plow. Is this profitable? Lavergne sums up the matter as to France, as follows; and we see no good reason why his remarks may not as well apply to America. "I am aware that the substitution of milking and butchering races for working animals, is not always practicable. I am not finding fault with those portions of our territory where cultivation is carried on with oxen, or even cows.—I recommend no sudden and rash change. I simply confine myself to stating facts as they exist, and believe I have demonstrated that by the sole fact of the almost entire abandonment of tillage by oxen, the soil of Britain—even including Scotland and Ireland—has in cattle reached a production double that of ours.—Such in Agriculture is the power of a correct principle when practically carried out."

#### KILLING CALVES FOR VEAL.

The French, like the Americans, consider veal a respectable article of food, which is hardly the case in England. If we maintain a large number of old cattle for labor, we have so much the less keeping for other stock, and are compelled to slaughter our calves, so that we are, as it were, obliged to eat veal, whether we like it or not, to turn our calves to some account. It is estimated that in France, of four million head of cattle annually slaughtered, two millions are calves, giving only about seventy pounds each of meat. The average weight of cattle slaughtered in France is about 225 lbs., while in England it is about 550 lbs.; the calves killed in France making most of the difference. The effect of using veal for food is manifest in another way. Calves for veal are usually kept exclusively on new milk, while in England they are taken from the cow and fed upon cheaper

fare. Besides, there are only produced in England as many calves as are wanted to be raised. Every calf will grow into beef; but a farmer breeding for oxen, or for cows exclusively, must select such calves as will answer his purpose.

One third of all the milk produced in France, it is said, goes to feed calves, and there can be no doubt that milk is much more profitably applied to feed human beings than animals. The breeds of cows in France are probably not inferior in milking qualities to those of Great Britain; but the climate is perhaps not so favorable, especially in the south of France. Where the sun is powerful enough to produce wine, the temperature is too high for the most favorable production of milk. The result of the different systems, with such allowance as should be made for climate, is that the dairy products of the United Kingdom with her three millions of cows, is estimated to be double in quantity that of France with her four millions of cows. Again, the cash value of these products being in England double their value in France; it is estimated that the dairy products of the former, are worth four times that of the latter. Lavergne makes all his comparisons with reference to prices as well as amounts; but we conceive this is hardly just to his own country. Although a hundred weight of beef may be worth in the English market twice the money it is worth in the French market, it certainly does not therefore possess double value for sustaining human life. But estimating dairy products in the two countries by quantity merely, we find in France but half the amount; and this is sufficient to lead to enquiry as to the causes of this result. The slaughtering of the calves, the working of cows, the maintaining of bullocks for labor after they have ceased to grow, are all opposed to the highest system of agriculture. There is, however, a heavy item to be placed to the credit side of the system of working oxen. They perform the labour which must otherwise be performed by horses or mules kept only for the purpose; and which not only eat and drink and are waited on through life, but return no meat in payment for their food at their death. The question of the profitableness of working oxen must still remain open, though Lavergne is decided in his opposition to it.

#### PIGS AND POULTRY.

As far as can be ascertained, the same difference exists as to swine in France and England, as we find in cattle; in the latter country the animal being killed younger than in France, although at about the same weight. This is a fact that meets us every where—that in England precocity or early maturity is the great desideratum. A large animal slaughtered young, is the idea of the English farmer; and manifestly it is the true idea. If you keep a pig two years to make him weigh as much as your neighbour's pig weighs in one year, you have lost at least one

year's keeping, as a general thing. But, it is estimated that the United Kingdom produces double the quantity of pork produced in France, a result accounted for by the fact that feed of every kind abounds in Great Britain, on all the farms.

In poultry, England is a long way behind France, the dampness of her climate being unfavorable to fowls. The English poultry yards are supposed to yield about five million dollars annually, while the annual product of eggs in France is said to be twenty million dollars, and of fowls as much more. A large portion of the population at the south of France subsist chiefly upon poultry so far as meat is required.

We intend in a future number to consider French Agriculture as it relates to horses and sheep, showing the comparative profit of sheep husbandry from wool and meat.

### Japan Lilies.

TO THE EDITOR OF THE AGRICULTURIST.—I wish to know if any of your readers ever cultivated the Japan Lily. Would they do me the favor of giving me their mode and experience through the *Agriculturist*?

I have had them, but they appear to run out like the Hyacinth. The *American Agriculturist* says: leave them out all winter, and cover them with leaves or rubbish of some kind. Is this the best way? What kind of soil, and when had they better be got in—spring or fall? I do not like to dispense with so fine a flower.

R. B. WERDEN.

Picton, 30th March, 1862.

### Berberries for Hedges.

TO THE EDITOR OF THE AGRICULTURIST.—I believe the world has been ransacked far and near to find something that would answer for a hedge in this country; but as yet every thing has proved a failure. The Osage Orange is too tender, the Hawthorn dies out in places, and the Buckthorn is liable to be browsed off by cattle in the winter. But according to my observations and experience, I think the common Berberry is the very thing we so much stand in need of, it being very hardy, easy of cultivation, and so offensive that no intruder will touch it. I therefore call the attention of the Fruit Growers' Association, Nurserymen, and all others that are interested, to this important and much neglected subject—give it a trial. Would like to hear of the experience of others through the *Agriculturist*.

R. B. WERDEN.

Picton, 30th March, 1862.

## Agricultural Intelligence.

### Spring Shows.

We are informed of the following Shows to take place this Spring. We request Secretaries of Agricultural Societies to inform us of the date of their exhibitions at as early a date as possible, so as to admit of publication in time to be of use to those interested:—

West Riding of York Agricultural Society, at Weston, April 23.

Reach and Scugog, at Fpsom, April 29.

Pickering, at Duffin's Creek, April 30.

West Gwillimbury, at Bond Head, April 30.

Brant Township, County Bruce, at Walkerton, April 28.

County Peel, at Brampton, May 1.

North York, at Newmarket, April 30.

County Halton, at Milton, April 23.

Western Branch, Haldimand, at York, April 23.

County Haldimand, at Cayuga, April 24.

County of Lincoln, at Grimsby, April 22.

Hamilton Horticultural Society, 1st Show, May 24.

East Middlesex, at London, April 28.

West Middlesex, at Strathroy, April 24.

East Riding of York, and Townships of Markham, and Scarboro, May 7th.

Darlington, at Bowmanville, May 2nd.

County Kent, at Chatham, April 29th.

### Flax Culture.

MEETING AT KINGSTON.

(From the Kingston Whig.)

According to public notice a large influential meeting took place in this city at the office of the Secretary and Treasurer of the Agricultural Society of the County of Frontenac, on Saturday the 12th inst., for the purpose of devising means for the promotion of the growth of Flax. His worship, the Mayor, seeing the crowded state of the room, kindly offered the use of the Council Chamber for the meetings of the Society in future. So great was the interest manifested in the growth of this article that, although the roads were bad, there were parties from every section of the country, as well as from those counties adjoining. Henry Robinson, Esq., took the chair, when several gentlemen spoke of the utility of paying particular attention to its growth, being much more profitable than the ordinary crops cultivated in this country. William Ferguson, Esq., who has had considerable experience on this subject, dwelt largely on the adaptability of the soil in this neighborhood for its cultivation, and also urged the necessity of making early preparations for the Provincial Exhibition of 1863. His Worship the Mayor spoke

strongly in favor of the enterprise, and hoped, before long, to see it one of the staples of the country.

There were several samples shown, both dressed and undressed, of excellent quality.

His Worship the Mayor exhibited some beautiful specimens of raw silk; also a handkerchief of very fine texture, manufactured from the fibre of the Pine-apple plant, and a Mexican Lasso rope made of the fibres of the leaf of the Cactus.

Moved by his Worship the Mayor, seconded by Mr. McClean, "That the Flax Dressing Machine be placed in the Mechanics' Hall, at the Crystal Palace, for the use of these counties and others."

Moved by Dr. Barker, seconded by Mr. Gibson, "That Henry Robinson, William Ferguson and Edward Jackson, Esquires, be a Sub-Committee to take such steps as they may think advisable for the management of said Machine."

It was unanimously resolved that a Committee, composed of the following gentlemen, viz.: Dr. Barker, Wm. Ferguson, and Isaac Simpson, Esquires, be appointed to draft an address to the City and County Councils, and to be distributed through the various townships for signature, asking for aid to put the Crystal Palace Grounds and Buildings in proper order and repair for the forthcoming Exhibition in 1863.

It was requested that parties requiring Flaxseed will leave their orders with either the Secretary or G. S. Hobart (Seedsman to the Society), on or before the first of May, in order that the required quantity may be procured.

Moved by Wm. Ferguson, Esq., seconded by J. G. Strachan, Esq., "That the thanks of the Meeting be given to his Worship the Mayor for his kindness in offering the Council Chamber to the Society for its next meeting."

The meeting adjourned sine die.

ISAAC SIMPSON,

Sec'y & Treas'r C. of F. A. S.

### The Future of the Royal Farms.

It is satisfactory to learn that, hereafter and for the future to bear the name of "The Prince Consort's" Farms, they will continue under the same immediate managers to illustrate the public spirit, enterprise, and perseverance of their former Tenant: and to furnish the same examples to landlord, tenant and labourer, as when in the late Prince Consort's hands. For owners of land the examples will be still maintained which he had given of the permanent improvement and efficient equipment of estates—in all the particulars of buildings, drainage, roads, and fences. Tenant farmers will see in continued operation, year by year, both the systems of steam cultivation he had adopted; and they will witness the progress of herds of Shorthorns, Devons, and Herefords which the Prince had established

with such ability and maintained with so much perseverance. On the last occasion of his visit to the Flemish Farm he was heard explaining the great expenditure which had been incurred by him as tenant, and the need and reasonableness of it in order to the attainment of high character for the valuable herd of Herefords which has on that farm been at length established. The reasonableness of this expenditure will year by year continue to appear, as, under the same system of management which he had laid down, these farms and their respective herds shall maintain in their career the reputation he had obtained for them. It is a touching illustration of the pious care with which his agricultural reputation will be guarded, and with which the many useful agencies will be maintained which this one small section of his labours includes, that all the Prince's intentions regarding farming matters, where known, will be literally carried out, and where they can be imagined they will be carefully observed. Thus we learn that all the stock which had been intended by him for exhibition at the Battersea Great Show, will, by Her Majesty's direction, still be prepared and sent—the Royal Farms will be opened to public inspection during the summer—and fields on Colonel Hood's suggestion have been set apart, in which during the week of the great show, steam cultivation will be shown in operation on one of them. The management of the Home and Shaw Farms remaining as heretofore under the immediate superintendence of Sir C. B. Phipps, K.C.B.—that of the Norfolk and Flemish Farms under the direction of the Hon. Colonel A. N. Hood—and the management of Windsor Park remaining in the hands of Major General Seymour and the Deputy Surveyor, Mr. Menzies—there is all the guarantee which devotion to the memory of their chief, knowledge of his intentions, and personal ability and zeal can give, that the public value and utility of these farms and the public interest in them will be maintained.—*Gardener's Chronicle.*

### Consumption of Roots.

Very few farmers take the trouble of weighing the quantity of roots consumed by their feeding bullocks. On a recent trial it was ascertained that a large three-year-old ox ate as much as 300 lbs. of yellow turnips per day, and when this quantity of good swedes, or even 100 lb. less, was given to him, he disregarded entirely his more natural food—straw—although it was constantly set before him. He seemed to prefer glutting down swedes, and in cold weather he had more or less of diarrhoea afterwards. If the same animal have the roots manufactured or pulped down into very minute pieces, and if this is mixed with finely chopped straw or chaff from the thrashing-mill, and fresh, one-half of the former quantity will fill him quite as well

and feed him much better, and his loose state of bowels will trouble him no longer. After careful experiments, we find that a large s'zed ox can be fed off upon six or eight stones of pulped turnips, with the addition of a few pounds of oil-cake. Ten tons of pulped proved equal in feeding value to 15 tons given whole and sliced, so three beasts can be kept in place of two, or, in other words, 20 acres of turnips are saved upon a 400-acre farm. The best plan, in our opinion, is to have the pulping and chaffing machinery driven by power, as it is up-hill work by manual labour, on a large scale especially. We should recommend Bentall's pulper, although it may be still subject to improvement. We have tried various pulpers, and we found the Perth prize machine worst of all; it may, however, be improved like others. As to chaff-cutters, there are so many in the market that it is difficult to hazard an opinion; but we should not hesitate in taking a prize machine from any of the Royal English Shows, from the great care with which their trials of machinery are conducted. For very young cattle or beasts of any age, when thus taken from grass, the value of a pulper is most apparent, for they will then go on feeding at once; and at that season it is an excellent plan to put the swede leaves through the pulper along with the bulbs. The quantity of straw or chaff consumed varies from 10 to 20 lbs. per day; and the whole theory of the success of this process of feeding appears to us to consist in the animal swallowing a much larger quantity of saliva than when eating whole or sliced roots. Every one must have noticed the saliva running from the mouths of their cattle when chewing cold roots. The entire immunity from choking or worrying is almost a most pleasant feature connected with the system, the conducting of which, no doubt, entails something beyond the usual expense for attendance and labour; but when two men and a boy (and 2 cwt. of coals per day) can prepare and carefully attend to 100 cattle, we consider ourselves amply repaid.—*Correspondent of Scottish Farmer.*

### Death of "Windsor"

We are sorry to have to announce the death of a very celebrated character, Mr. Richard Booth's Windsor, who expired, on Thursday, the 13th. "Scour," which could not be stopped, set in, and carried him off quickly. Windsor was calved in October, 1851, and was accordingly, upwards of ten years old. His honours in the show-yard were many and well deserved. He won the first prize in the calf class at the Yorkshire Society's show at Sheffield in 1852, and the first prize at the Durham County show in the same year; the first prize as a yearling, at the Royal Agricultural Society's show at Gloucester in 1853; and the first prize at the Yorkshire Society's show at York in the same

year; the first prize as a two-year-old at the Highland Society's show at Berwick in 1854; the first prize at the Royal Irish Society's show at Armagh; and the first prize and medal and silver cup at the North Lancashire show in the same year; the first prize as an aged Bull at the Royal Agricultural Society's show at Carlisle in 1855; and the first prize at the Yorkshire Society's show at Malton in the same year. He was by Crown Prince, and his dam, Plum Blossom by Buckingham, obtained the first prize as the best cow at the Royal Society's shows at Windsor in 1851. For physical reasons, which need not be more particularly noticed here. Windsor in the earlier part of his life, had failed to be a prolific sire. Towards the close of his career, however, he became fruitful, and was certainly one of the most impressive sires that ever left the pastures of Warlabby. Though, with many others, we always thought him a trifle too narrow, he had a magnificent frame, with a fore-end that almost touched the ground, quarters long and well furnished, a back straight and firm, ribs springing out finely and roundly, unexceptionable loins, and thighs somewhat more perpendicularly shaped than those of Warlabby bulls generally are. His disposition, too, was beautiful; he was as quiet as a lamb. Very few males, either at Warlabby or elsewhere, owe their existence to this famous bull. Sir Roger "calls him father;" and Valasco, as Mr. Booth states in the herd book, was either by him or Crown Prince; it is not known which. Windsor the 2nd also, out of Satin, was his son. Mr. Carr who rented him for a year, at the large sum of 200 gs., had several bulls by him. Of these Don Windsor remains at Stackhouse; Young Windsor became the property of Mr. Bolton, of The Island, near Wexford; Imperial Windsor went in September to Mr. Foljambe's, at a rent of 120gs. a year; another, Fitz Windsor, was bought by Mr. Logan, of Maindee House, Monmouthshire; and Royal Windsor, out of Queen Charlotte, by Hamlet, belongs to Mr. Housman. These bulls, and any others by him, possess now a peculiar value.—*Bell's Messenger.*

NOVEL IMPORTATION OF STOCK.—The *Mermaid*, which arrived from Canterbury last week, had on board 38 sheep from Mr. George Rich's celebrated merino flock, consisting of 28 rams and 10 ewes. Some of them are intended for the breeding establishment of the Emperor Napoleon at Rambouillet, according to the arrangement concluded with Baron Daurier by Mr. Rich on his visit there in 1859. The remainder are for the improvement of Mr. Rich's own establishment in England. The sheep will, no doubt, obtain for Mr. Rich the recompense he merits in the full appreciation of the admirable qualities of his New Zealand-bred flock by those who are well able to form an opinion.—*Australian and New Zealand Gazette.*

### The Lonk Sheep at the Show of the Royal Agricultural Society of England at Leeds.

When at the show of the Royal Agricultural Society of England at Leeds last year, amongst the numerous lots exhibited we noticed a variety of mountain or hill sheep called Lonks, very closely resembling the Scotch black-faced, but which, upon nearer inspection, exhibited much finer proportions, and the wool a finer staple. The prizes offered by the Leeds local committee in the section for the mountain breeds for the best Lonk ram and the best pen of 5 Lonk ewes were awarded Mr. Jonathan Peel, of Knowlesmere Manor, who gives the following account of them:—

"The Lonk is an old indigenous breed inhabiting the Lancashire and Yorkshire hills, the purest blood being in the neighbourhood of Keighley, Rochdale, and also of Pendle Hill, near Clitheroe. They have long been in high esteem in their own district, and having been improved of late years, are gradually extending themselves and taking the place of mixed breeds on the neighbouring hills. The rams are now much sought after to improve these mixed breeds, the attempt being by continued crosses to work the flocks gradually towards the pure Lonk type. They are perfectly hardy, excellent mothers, and very prolific. The wool and flesh are of very superior quality. From experience I am able to say that in all these qualities they far exceed the black-faces. I lost much time in the endeavour, by crosses with Southdowns and Shropshire Downs, to strengthen their weakest points, but was unsuccessful; now, therefore, I have reverted entirely to Lonk, and have swept away every prize at the last year's shows, and sold my draft ewes at two guineas each. Few but drafts are ever to be bought, nor, of course, do they often fetch the price I got for mine. Thirty shillings would, perhaps, be about the price of good ones. I have been requested to send up fleeces to the Great Exhibition, and shall exhibit in all the 'mountain sheep' classes at Battersea."

Since the great show at Leeds, we have been anxious to find out something concerning this very thrifty and seemingly hardy breed of sheep, and, under correction of our English friends who may be better able to throw light on the subject, we are in some degree impressed with the idea that though the foundation has been laid on the original indigenous breed bred on the Lancashire and Yorkshire hills and the hill country stretching away to the borders of Scotland, they have been with consummate judgment crossed with some other breed, which, while retaining the original handsome and characteristic markings of the old race, conferred a greater roundity of form and greater aptitude to fatten. We are somewhat fortified in this opinion by Luccock; who says, in remarking on the Lanca-

shire sheep, "Some flocks are kept on the mountains, in a very poor and neglected condition, and others are found on the low and fertile plains of the west; but the stock of sheep is small and ill attended, and the wool is very dirty and coarse and kempy, and the greater part possesses all the bad properties of the neglected mountain sheep." Youatt says, "This is very severe criticism, and doubtless is perfectly true at the time. More attention is now paid to sheep husbandry, but not so much as it deserves."

"The prevailing breed is what is called here the Woodland horned sheep—a variety of the heath or mountain sheep, which, beginning to appear on the hilly country, are spread over the whole north, to the very extreme of Scotland. They are found pure, or with almost every variety of cross; but the principal crosses, and which are decided improvements, are the Leicester or the Southdown, and by means of which both the carcase and the wool are increased in weight and value." Again, "The two ranges of hills, the Western and Eastern Moorlands occupy the greater portion of it (North Riding of Yorkshire). They are cold and desolate, and covered with heath; but the valleys by which they are intersected contain much good soil, and are well cultivated. The sheep that are found on them live on the open heaths all the year round. Their summer food at least, and often their winter food too, consists of heath and rushes, and a few of the coarsest grasses. The long-woolled sheep could not live there, and their owners have wisely refrained from contesting the possession of these hills. The moorland sheep are horned, and have black or mottled faces or legs. Their horns spread wide. Mr. Marshall says that the covering of their buttocks is mere hair, resembling the shag of the goat more than the wool of a sheep; but this is considered a mark of hardness. They are small, being not much larger than the heath sheep of Norfolk. Ewes weigh from 7 to 10 pounds per quarter, and the wethers from 10 to 14 pounds. Mr. Marshall was a good judge of sheep, and there can be no doubt that the description was accurate at the time when he wrote; but the farmers have become better informed and the sheep have materially improved." — *Irish Farmer's Gazette*.

### Evil Effects of Pampering Cattle.

We learn from recent English papers that Mr. Booth's celebrated short horn cow, *Queen Mab*, which obtained either first or second prizes at the National shows both of England and Scotland, has proved, in consequence of too high feeding, incapable of breeding. We saw this animal at the English Society's Show at Canterbury, in 1860, when doubts were gravely expres-

sed by competent judges on this point. Captain Gunter's Shorthorn cow, which won the first prize at the Royal at Leeds last year, is also disqualified, from the same cause. The splendid Bull *Statesman*, which we saw at the Royal Irish Show at Cork in 1860, has proved himself impotent as a stock-getter from the stimulating system to which he has been subjected. It is true these are but isolated instances, but it will be well for short horn men to be alive to them, or the fair fame of that distinguished breed will, by degrees, become tarnished. On this side of the Atlantic, Durham cows especially, may be occasionally seen at exhibitions in much too high a condit on for safe breeding purposes. This is owing more to the absurd manner in which these animals have been treated, than to any innate defects of their own. "It is," remarks the *Mark Lane Express*, "the suicidal forcing system, which we have so long protested against, that is destroying the fair fame of the Shorthorns. The real value of a brood mare or a brood cow centres in her ability to breed, and the Royal Agricultural Society will yet have to face this abuse with more determination."

## Horticultural.

### Flower Beds and Bedding Plants.

*Read before the Hamilton Horticultural Club by Mr. Geo. Laing, Gardener, of that City.*

MR. PRESIDENT AND GENTLEMEN:—The winter that is now, we trust, nearly past, although long, has been favourable in many respects, particularly so, for horticultural in-door operations, the keeping of plants, &c. Such being the case it is to be hoped that all will be well supplied with plenty of good things for the coming season, so that the pleasure grounds, gardens, and flower beds, will be better and look gayer than they ever yet have done. Adverse as the times have been of late, Horticulture has continued to advance. This is encouraging and ought to stimulate all to push onwards in the good work—there is still much to do.

In my paper on flower beds and bedding plants last year, I noticed in a general way most of the kinds in use; their culture and management, and as I have been called on for another paper this year, on the same subject, it is not necessary for me now to touch much on any of the particulars I then noticed. In looking over the report of that paper in the *Canadian Agriculturist* of 1st of May last, I find that no notice was there taken of the bulbous flowering plants, a class that is very full of interest and very worthy of cultivation. Mr. Bruce in his paper to this club last month, so fully described this class, their nature, habits and culture, as to render any thing from me here unnecessary, further than to remark that

they are very requisite in all places for early flowering. In passing over the bulbs the *Anemone* and *Ranunculus* have occurred to my mind as worthy things, they are very much appreciated in the Old Country for their beauty and early flowering, but here they seem to be little noticed. I believe this in some measure may be attributed to a fear of our long and hard winters, and the failures of a few that have tried them. I am inclined to think they will do well if properly planted in fall in a good sandy loam, before the frost sets in, covering the beds over with a good layer of light stable manure or tree leaves, or a mixture of both, laying boards on the top to turn off the rains, otherwise early in the spring put them into small pots, start them either in a frame or pit with a slight heat, when a little advanced and weather permitting plant them out into a suitable situation.

This season I hope that a greater effort will be made with the shrubby *Calceolarias* as a bedding plant. It appears to me strange, when they do so very well in the green houses that they won't do outside; it is said that our climate is too hot for them, if so put them in a shade. There are now many excellent new varieties; all very much praised in England for their bedding qualities, their hardiness, profusion of colours, rich and continued flowering habits, properties that I think ought to encourage their cultivation in this country. In the ribbon border system, which I shall here introduce, the *Calceolaria* is almost indispensable.

Ribbon borders, pannelled beds and linked chains, &c.—strange things to be made of flower plants, but such is the case, and very beautiful they are. In the Old Country for some years, this has been the leading feature in floriculture, over the length and breadth of the land. Novel as it may appear it is no less true, and worthy of commendation. Much has been and is being made of it where it has been and is practised. Very greatly has it been praised, but for all, and in all, it is nothing more or less than arrangement of colours, foliage shades, and regularly proportionated growing plants. Simple as it may appear it requires both taste and judgment to execute it properly. The principle is good and will answer well in any place, whether large or small, no doubt the more extensive and diversified the grounds and gardens are the better will be the effects. In this as in all other modes of planting, the effects depend much on the nature and formation of the grounds, but this is not now under consideration. My present object is, simply to convey a few ideas that may prove beneficial to those of our energetic gardeners and amateurs who have made up their minds to become ribbon men for this year.

First then, each and all individually will say to himself before he begins, in what manner shall I plant these grounds, gardens, &c., to have the most pleasing and expressive effects, and to produce the best and most continuous

show of flowers during the season? He thinks: the nature of the grounds, borders and beds, are all familiar to me, the attractive sights from the mansion house, drawing room windows, conservatory, and all other conspicuous points I know, in all their bearings. He then considers, his mind gets absorbed on colours, lights and shades, and all that is beautiful, by and by in ecstasy he exclaims, I see it all prospectively! and then to obtain it in reality he commences his arrangements nothing down something such as the following: The large border leading towards the garden, I shall ribbon with some of my geraniums, such as *Brilliant*s, *Tom Thumb*, and *Flower of the day*, with other fine things, here my *calceolarias* will come in first-rate, with *Alyssum* variegated as outer edging if I can get it. The borders on each side the main walk from the mansion house I shall also ribbon, with some of my *Heliotropiums* and fine hardy dwarf *Lantanas*, and the choicest of my *verbenas*, with *cerastium tomentosum* on the one side and blue *lobelias* on the other. The beds in front of the mansion house, I shall panel, this will be in nice keeping with the house. This panelling is rather a ticklish piece of work, but I shall manage it, my ground work I shall carefully frame, raising all my centres, have no sunk panels, bearing always in mind that each member of the order properly distinguish itself. With this view, for my framing purposes I shall use plants of a close texture, dark green foliage with bright flowers of very distinct colours, the panels of lighter shades, close and procumbent plants with flowers distinctly different from the frames. The small narrow stripes on each side the serpentine walk leading to the summer house to be lined with all the finest dwarf and choicest flowering things that I can lay hold of. The figures in the distance I shall group with my largest plants.

In the manner described, the whole being noted, all enumerated and duly considered, when the planting comes on the operator is enabled to proceed systematically and in order. It is not for me here to particularize, name plants or recommend colours for this purpose. every ribboner and paneller must choose for himself. Our lady friends can aid much in the furtherance of this object being all good judges of colours and ribbons. Most of the gardeners and many of the amateurs here are well stocked in *verbenas*, *heliotropes*, *petunias*, &c., and of the older kinds of bedding geraniums, but few have yet obtained many of the new varieties, such as *Mrs. Pollock*, a fine scarlet, one of the best geraniums out, and good for all purposes. *Burning Bush*, valuable either for the flower garden, green house or conservatory, its peculiar leaf tint when grown as a pot plant gives a charming effect under glass. *Golden Tom Thumb* is here in all his glory, with his fine golden broad margins increasing in beauty with the growth of the plant, showing a bright green disc, dark zone, and a mass of bright scarlet flowers. Perfection, of

dwarf spreading habits with pure white margin, bright scarlet trusses, good either for ribbon lines or groups. *Golden Harkaway*, with its beautiful golden foliage and fine flowers, is a first-rater for vases, small beds or margins. *Alma*, with green disc and noble scarlet trusses. *Golden Chain*, with golden margin finely contrasted with a bright green disc and dark zone, producing an abundance of large trusses of dark shaded cerise blossom. Attraction, a fine variety with white margin fine rose zone or inner belt, green disc with pink trusses. Many more of the variegated and other new varieties might be mentioned, a few of which would be a very great acquisition to our bedding stocks.

*Gazania Splendens* is now plentiful, it makes a very nice bed and answers well in vases. Try and have the pansies in right compost this year and their beds in a shaded place. Mr. Dean says, in the *Florist and Pomologist*, published in London, February last, "that our favourite flower runs a great risk of finding a powerful rival, in the new and fancy forms recently introduced under the designation of fancy or Belgian pansy," he says, "that they are fast approaching the circular form combined with substance, which the stern laws of the florist demand before they can be admitted into their circle, wonderful things are doing now a days amongst the flowers by cross-breeding."

This same kind of fancy pansies is to be seen in Bruce and Murray's Nursery in this city; they are rather thin in substance, but well formed and pretty.

I may again let you have more on the bedding subject.

### Deep Planting of Trees.

Most writers on fruit culture are agreed on the injury resulting from deep planting. Whether in noting the assertion, they all have clear and well defined ideas of what deep planting really is, is not so apparent. I rather suspect that the term is frequently employed by many who could not tell you whether a certain depth was too deep or the reverse. In fact it is one of those very indefinite and vague terms that get into print and are used "promiscuously." Now, I here put it to those who may hereafter use the term "deep planting," to state positively what it means in connection with their subject. It is frequently given as an illustration, that when a seed, an acorn for instance, drops on the ground and vegetates, the roots and stem of the future tree will be properly situated as regards depth of planting. Notwithstanding that this and similar statements are constantly being made, we never see the gardeners sowing their peas or any other seeds on the surface. On the contrary, all advices recommend covering more or less in depth with the soil, and very properly too, as all who ever attempted raising plants from seeds are fully aware.

The necessity of keeping the roots of plants within the influence of the atmosphere, is one of the most important truths in culture, but it does not follow that they should be kept on the surface of the soil. The impracticability of maintaining roots in a healthy condition, and in a medium where they can perform their offices, on the mere surface, must be well understood by all cultivators. Frequently in dry summers the soil is entirely destitute of moisture for a depth of twelve or more inches, and even if possible for a tree to survive the summer, the injury from freezing in winter would act very fatally. It may be said that mulching the ground with six inches of manure, charcoal, or some other non-conducting matter will obviate this difficulty, but where is the soil that will preserve a porosity after a series of heavy rains in summer, or the consolidating tendency of heavy winter snows. All experienced cultivators are convinced of the propriety and absolute necessity of keeping a loose, free surface soil, and the thorough beneficial effects of the harrowing and surface stirring; these effects are too apparent to be gainsayed, and this stratum of stirred soil must be above the roots. Indeed there is no better protection against the drying out of root moisture than six inches of well pulverized soil, leaving out of the question the undoubted benefit gained by the amount of plant food liberated by exposing all portions of soil to the decomposing influences of the atmosphere.

On wet clayey soils, where draining should be, but has not been executed, and where trees are desired, it is a practice indited by common sense as well as by physiological reasoning, to plant shallow. By planting shallow it is not meant that the roots are to be superficially and imperfectly covered, but that instead of digging a hole in the ground, the tree is set on the surface and soil brought to it, covering it with five or six inches all over the roots. On dry and well drained soils, the plants are set in the soil, so that the roots are sufficiently covered, but yet it is not to be understood the latter are deep planted. No, both are properly planted according to the circumstances prevailing in each case.

Other circumstances besides the above will occasionally influence the depth of planting. Dwarf apple and pear trees grafted on the Paradise and Quince stocks, have to be so planted that the stocks are thoroughly covered with soil, so that they may be put out of the reach of the borer. These trees are grafted so that this practice can be adopted. The necessity of proper grafting in this case has been well shown by Mr. Mead, the present Editor of the *Horticulturist*, who was induced to purchase dwarf pears grafted on stocks twenty inches high, and in order to plant them according to rule, had to insert them nearly two feet in the ground to ensure the covering of the junction. This was a very definite case of *deep planting*, and as the

trees mostly all died, it left not a doubt as to the impropriety of the practice. But then it does not follow that we should stretch to the opposite extreme and plant so shallow as not to properly cover the roots. My own practice has been much modified as observation and experience enables me to judge that that roots of trees cannot long be kept without injury on the immediate surface of the soil.—W. S. G.—*Country Gentlemen*.

## The Dairy.

### Butter and Cheese.

We have been deeply interested with Miss Martineau's charming little work, recently published, entitled "Health, Husbandry, and Handicraft," which contains a selection of her papers, contributed during the past few years to the pages of "Household Words," "Chambers's Journal," and "Once a Week." Most agricultural topics are discussed, such as pigs and poultry, drought and drainage, butter and cheese, and dairy management generally. In the volume before us the need of butter as food is illustrated from the habits and economy of nations, under every latitude on the surface of the earth; but the butter-making described is chiefly that of Ireland, while the cheese-making is chiefly that of Cheshire.

The butter and cheese making to which, in this article, we would refer, are those which are carried on together in many of the large English dairies, where a portion of the cream is taken from the milk, lest the cheese made from whole milk should heave in curing. This is the practice in most Gloucestershire dairies. A dairy of 100 cows will yield probably  $1\frac{1}{2}$  cwt. of butter weekly in the height of the season; the skim milk of a small portion set apart being added to the whole milk morning and evening, before it is set for curd.

The difficulty of making a cheese of whole milk, which shall not heave, is overcome in Cheddar cheese-making:—and the characteristic feature seems to be the scalding of the curd, after it has been broken, at a much higher temperature than is allowed in other dairies. A Cheddar cheese is worth 80s. a cwt.; a cwt. of good Gloucestershire may fetch 65s.; the difference between the two is not, however, clear profit to Cheddar dairymen. For the Gloucestershire

ter dairy yields a pound or a pound and a half of butter per cow weekly, in addition to ner cheese, while the produce of the Cheddar dairy is wholly cheese, or cheese and bacon.

As the dairy business is yearly becoming of more importance to Canadian farmers, the following short account of their principal methods of making cheese in England, condensed from Miss Martineau's book, will not be uninteresting to our readers:—

1. **GLOUCESTER CHEESE.**—Under ordinary management, the Gloucester cheese is made twice a day. The morning's milk is heated or cooled to about 80° in one or more large vessels of from 80 to 100 gallons; a pint and a half or thereabouts of rennet is added to every 100 gallons; in an hour's time or so, when the curd has set, the curd-breaker, a wire sieve fixed on the end of a pole, is slowly and repeatedly drawn hither and thither through the mass, the whey is baled out, the curd is pressed by the hand, crumbled fine, and placed in a cloth and in the cheese vat under a press for twelve hours; it is then salted and turned, and again put under the press. It is kept there as long as there is pressure for it, and afterwards transferred to the dairy shelves, where it is turned at intervals, and where it gradually ripens. The whey baled out of the curd-tub stands and throws up a cream from which an inferior butter is made. In addition to the cheese, some 4 cwt. a-piece made per cow, and the 36 lbs., or thereabouts, of milk and whey butter made per annum, they calculate in Gloucestershire on fattening a pig of about 12 stone for every three cows upon the waste whey, &c., of the dairy.

2. **CHESHIRE CHEESE.**—The following may be taken as the ordinary history of a Cheshire cheese:—The cows are milked at night, and the milk poured through a sieve into tin pans on the floor of the milk-house. This milk is skimmed in the morning, and then poured into the large tub where the curd is "set." As the morning's milking proceeds, the pailful are brought one after another and poured through the sieve into this tub. A pan of milk is warmed by floating in a boiler in the dairy, and when sufficiently hot the whole of the cream just taken is mixed with it, and the whole thus warmed is poured at last into the tub, which thus contains the whole milk, cream and all, of both "meals." The temperature of the milk, when well mixed, should be about 75 degrees Fah. The liquid colouring matter, "annatto," about half a gill, or half an ounce of the solid colouring matter dissolved in half a pint of warm water, is added to the 100 or 120 gallons which may be then in in the tub as the produce of 40 cows; and the rennet, about a pint of brine, in which two or three little bits of the prepared calves' vells have been steeped over night, is added to the milk, which is then left for an hour covered up till the curd has fully formed. It is then cut slowly with a wire curd-breaker, and the curd

sinking, the whey is baled out; the curd is collected and squeezed both by hand and the direct pressure of a weight above a board placed upon it, and the last of the whey being removed, it is lifted either into a basket or into one of the large Cheshire cheese vats ("thrusting tubs,") pierced with holes for the further escape of fluid—the lower part being a wooden cylindrical vat, and the upper a tin cylinder slipping into it as the curd on pressure sinks. After a certain pressure in this form, the curd is removed, and cut and broken by hand or by a curd mill, and from one to two pounds of fine salt is scattered over it, according to the weight of the cheese; about 1 lb. to every 40 lbs. of cheese is a common quantity. The whole curd being then re-broken is refilled into the vat, into which a cheese cloth has previously been placed. It is then put gradually under pressure, which, after the second or third day, amounts to nearly a ton weight upon each cheese. Every day the cheese is turned and wrapped in fresh cloths, and on the 7th or 8th day of this treatment, or as soon as dry, it is removed to the loft, and there swathed around with a linen band and placed on a bench, being turned occasionally until it is ready for sale. The Cheshire cheese is thus a whole milk cheese.

3. **THE CHEDDAR CHEESE** is also a whole milk cheese. It differs in its manufacture from the others chiefly in the scalding of the curd. Immediately after the morning milking, the evening and morning milk are put together into the tub. The temperature of the whole is brought to 80 degrees by heating a small quantity of the evening milk. A small quantity of annatto is put into the milk along with the rennet, and in an hour, the curd having set, is partially broken, and a small quantity of whey is then drawn off to be heated. The curd is then minutely broken, and as much of the heated whey is mixed with it as suffices to raise it to 80 degrees, the temperature at which the rennet was added. In another hour, a few pailfuls of whey are drawn off, and heated to a higher temperature than at eight o'clock. The curd is then broken as minutely as before, and after this is carefully done, an assistant pours several pailfuls of the heated whey into the mass. During the pouring in of the whey the stirring with the breakers is actively continued, in order to mix the whole regularly, and not to allow any portion of the curd to become over-heated. The temperature is thus raised to 100 degrees, and the stirring is continued a considerable time, until the minutely broken pieces of curd acquire a certain degree of consistency; the curd is then left half an hour to subside. Drawing off the whey is the next operation, and the curd is carefully heaped up, and left for an hour with no other pressure than its own weight. The whey drips towards the side of the tub, and runs off at the spigot, no pressure being applied. The curd is cooled to 60 degrees, and put into the vat under pres-

sure for half an hour; at this time the curd is broken a little by the hand, and thrown upon a lead cooler, until it is brought down to the desired temperature. The after management of the cheese resembles that of the Cheshire. A little salt,  $1\frac{1}{2}$  lbs. per cwt., or thereabouts, is added to the crumbled curd, and it is mingled and broken by the curd mill.

The striking circumstance connected with all these methods of making cheese is that neither in the curd, nor the butter, if any, one in the bacon made by the consumption of the whey are all the contents of the milk, according to the analysis of the chemist, returned to the farmer. Mr. Harrison, of Frocester Court, Gloucestershire, has thus called attention to this important fact:—"The quantity of bacon fatted from the whey shows that there must be an immense quantity of valuable food left in it. But even allowing the whey to be worth £2 per cow, this is not half of what its contents would be worth could they be extracted and prepared in the form of cheese and butter for human food. There is here a broad margin for experimental inquiry and improvement. On this point I have worked out the following from the records of our dairy. I take a single year, when the yield of milk was 31,700 gallons, weighing 321,000 lbs., and containing therein, by analysis, 12,480 lbs. of casein, and 11,556 lbs. of butter; now the dairy produce was of cheese 25,424 lbs., and of butter 3466 lbs.; and these contained, by analysis, 9765 lbs. of casein, and 8,366 lbs. of butter; leaving 2715 lbs. of casein, or 22 per cent., and 3190 lbs. of butter, or 27·6 per cent. unaccounted for.

"Such a calculation is of course only approximate. For instance, instead of taking the double Gloucester analysis for the cheese that was made, it would have been more correct to take the Cheddar analysis, as we endeavoured to make the cheese much richer than in the former years. This would reduce considerably the large apparent loss of butter.

"The chief point is to see clearly that there is an enormous quantity of casein and butter which we do not extract from the milk. Can no means be devised for extracting them more thoroughly? I have no doubt the application of heat on the Cheddar system will do much, but a maker of this cheese was astonished to see the quantity of curd that resulted from boiling a small quantity of his clear-looking whey. I believe that the loss results from the system of minutely dividing the curd after it is set, and that it comprises some of the richest of the casein and butter. It is well known how much a successful result depends upon the gentleness with which this operation is performed."

The enormous loss which analysis indicates in the case of Mr. Harrison's dairy is probably, as he says, beyond the truth; but the truth itself must be bad enough; and the subject is one which much needs investigation by the agricul-

tural chemist. It is satisfactory, therefore, to learn that Dr. Voelcker, the chemist of the Agricultural Society of England, has been for some months engaged upon it. He gave the main results of his research in a recent lecture in Hanover square, and we look with great interest to its appearance in the next number of the Society's Journal.

## Veterinary.

### Epidemic among Dairy Stock in Britain

(From the *Mark Lane Express*, Feb. 23rd.)

The new number of *The Veterinarian*, for February that is, has the following amongst other FACTS AND OBSERVATIONS of the month:—"During the past few weeks *Eczema Epizootica* has prevailed to a very serious extent in the dairies of the metropolis and the surrounding districts. Many cows have died, and a far greater number have been disposed of at a great reduction of price, in consequence of becoming affected with mammitis, ulceration of the feet, &c., as sequelæ of the malady. The purveyors of milk have been put to the greatest strait to find a sufficiently supply for their daily customers, and healthy cows from the country have been purchased by them at fully twenty per cent. above their ordinary value."

Significantly enough Mr. John Gamgee, the Principal of the New Veterinary College in Edinburgh, has just taken up the same subject. On only Wednesday last he delivered a public lecture in Edinburgh on the present traffic in unwholesome meat and milk, a full report of which is given in the *Edinburgh Veterinary Review* for this month. The Northern Professor is able personally to corroborate the alarming character of the cattle disease as it is now raging in the dairies of the metropolis: "I have recently visited London, where the complaints amongst the cow-keepers are terrible. Few I am told, are paying their way; some may be thriving, but entirely by the system of selling diseased cows to the butchers, or by keeping very few cows, and 'drawing in' their milk. By this is meant purchasing from the dealers who receive largely from the country. I spoke to one of these dealers; and disease existed amongst the cows to such an extent, that he said, although nothing can be more profitable than cow-keeping if the cows retain their health, we now lose seriously, and keep up our trade by buying from all sources. Constantly, throughout London, have the lung and apthous diseases existed for many years past; they prevail largely now, and about a month ago, epizootic aphthæ broke out; it has spread north, and is at the present time in Edinburgh."

It is satisfactory to see the Profession alive to the evil now so alarmingly on the increase; but

while *The Veterinarian* is content, at least for the present, with a simple record of the fact, Mr. Gamgee goes elaborately into the subject as a public question. It is not merely a critical time for dairymen, butchers, or cattle dealers; for the vital interests of the community are equally at stake. With the spread of the disease we shall have a proportionate extension of the trade in diseased meat and milk. The sale of unwholesome beef and mutton has often ere now been dwelt upon, and by no one with more weight than Mr. Gamgee himself. "Within a comparatively recent period" let us here see what "the so-called murrain" has done amongst the dairies:—"The eruption occurs in the mouth, on the teats, and on the feet. If calves are permitted to suckle cows, or if pigs drink the warm milk, they are seized with violent irritation of the throat and alimentary canal, and die." It would not be to the dairyman's profit to attempt to consume such poisoned produce on his own premises; while as we fear is but only too probable, should he dispose of it in the usual manner to the public, it may be with such consequences as these:—"Many instances, but especially experiments by Jacob and by Professor Hertwig of Berlin, have shown that an eruptive fever develops in man after drinking such milk. If infants, who should have an abundant supply of this nutritious product, receive it thus poisoned, what must be the result? Admitting that it may be very rare that a child has been killed from such a cause, we certainly cannot countenance any practice likely to inflict the slightest pain or injury on tender babies."

Surely here is matter for some very serious alarm, and calling for some as immediate investigation. The disease in the dairy is spreading. Can we say from any known cause? Simply, then, because the most certain means are adopted, not for prevention, but contagion. When a dairyman finds a cow affected he feeds her up, and sends her into the open market, where she stands amidst herds of others, amongst which the healthy, fresh, country cattle are the most susceptible subjects. The very obvious commentary on such a course is that it should be at once prevented by due inspection and careful attention, so that no suspected animal should be suffered to mix with others until properly passed—or, briefly, either killed or cured. How answers Mr. Gamgee to this? "The inspectors to be found in our large towns, and who have been fleshers (butchers), weavers, servants, policemen, &c., are unfit for such duties, which professional men can alone accomplish. To accuse such men that they do not do their duty because they do not check the traffic in diseased animals, is equal to accusing a man of a crime because he won't jump over the moon. I unhesitatingly say, what I have repeated a thousand times over, that the whole system of inspection is a farce." As regards any remedy, the lecturer spoke out quite as strongly against

the members of his own profession. We are by no means anxious to pit one "school" against another; but when, with the disorder raging as it is now admitted to be in London, we are told what our London authorities are, or rather are not doing, becomes us to ascertain how far the charge is warranted. If neglect is thinning our dairies and poisoning our people, amendment is at least to some extent in our own hands. Mr. Gamgee indignantly asks: "Is it not monstrous that with diseases so dangerous and so rife in our land, there is no infirmary in the whole length and breadth of her Majesty's dominions where half-a-dozen diseased cattle are ever seen—a stray case occasionally? I believe I saw three diseased cattle in three years that I was at the London Veterinary College, and so eager was I for practical instruction, that I hunted the dairies myself to see, to treat, and of course to kill perhaps oftener than I could cure. What would the public and our medical men say if medical schools had no hospitals? A scanty variety of patients, chiefly a few lame horses, are not likely to teach our students how to benefit the farmer; and, as the Principal of one of our Veterinary Colleges, I attack the system which condemns the public to eat diseased cattle, whilst no effort is made to teach men how to control or prevent disease."

### How to Choose a Farm Horse.

John Brunson, in a late issue of the *Ohio Cultivator*, lays down the following rules to be observed in the choice of a horse for the purposes of the farm:

"The farmer requires a horse that can take him to market and around his farm, on which he can occasionally ride for pleasure, and which he must sometimes use for the plow and harrow. First to notice are the eyes, which should be well examined. Clearness of the eye is a sure indication of goodness. But this is not all—the eyelids eyebrows, and all other appendages, must be considered; for many horses whose eyes appear clear and brilliant, go blind at an early age; therefore, be careful to observe whether the part between the eyelids and eyebrows is swollen, for this indicates that the eye will not last. When the eyes are remarkably flat, sunk within their orbits, it is a bad sign. The iris or circle that surrounds the sight of the eye, should be distinct, and of a pale, variegated cinnamon color; for this is a sure sign of a good eye. The eyes of a horse are never too large. The head should be of good size, broad between the eyes, large nostrils, red within, for large nostrils betoken good wind. The feet and legs should be regarded; for a horse with bad feet, like a house with a weak foundation, will do little service. The feet should be of middle size and smooth; the heels should be firm, and not spongy and rotten. The limbs should be free from blemish.

es of all kinds, the knees straight, and back sinews strong and well braced. The pastern joints should be clean and clear of swellings of all kinds, and come near the ground; for such never have the ring-bone. Fleahy-legged horses are generally subject to the grease and other infirmities of that kind, and therefore should not be chosen. The body should be of good size, the back straight, or nearly so, and have only a small sinking below the withers; the barrel round, and the ribs coming close to the hip joints. The shoulders should run back, but not too heavy; for a horse with heavy shoulders seldom moves well. Chest and arms large. A horse weighing from 1,300 to 1,400 pounds is large enough for a cart horse; from 1,000 to 1,200 is large enough for a farmer's horse; from 1,000 to 1,100 is heavy enough for a carriage horse. I should advise every one to get some experimental knowledge of a horse before purchasing."

### Miscellaneous.

**STRENGTH OF THE TIGER.**—The strength of the tiger is prodigious. By a single cuff of his great fore paw he will break the skull of an ox as easily as you or I could smash a gooseberry, and then, taking his prey by the neck, will straighten his muscles and march off at a half trot with only the hoofs and tail of the defunct animal trailing the ground. An eminent traveller relates that a buffalo belonging to a peasant in India having got helplessly fixed in a swamp, its owner went to seek assistance of his neighbours to drag it out. While he was gone, however, a tiger visited the spot and unceremoniously slew and drew the buffalo out of the mire, and had just got it comfortably over his shoulders preparatory to trotting home, when the herdsman and his friends approached. The buffalo, which weighed more than a thousand pounds had its skull fractured, and its body nearly emptied of blood.—*Wild Sports of the World.*

**MODE OF LIVING IN ICELAND.**—The walls of the room are still of the colour of the wood, but it is easy to see that they are new. Within a year, the peasant remarks, they will be handsomely painted. In the backgrounds our searching glance detects a small alcove; and a clean bed is visible between the half-drawn chintz curtains. The space between the windows is occupied by a table and several easy chairs.—Against the walls, to right and left stand the newly polished commode, and a species of secretaire in oak. The conversation between ourself and the peasant certainly progresses but poorly as we both maltreated Danish; but, ere long, his daughter appears, an underset girl with bright red plump cheeks, and the stumpy nose peculiar to the daughters of the land. She is busy in preparing the meal. The tablecloth is of snow

white linen, the service of the finest china, and the spoons of heavy silver. Soon a tureen of rice-soup steams on the table. The following dishes are magnificent: Trout with their yellowish-red meat, smoked mutton, eggs, supplied by the ducks dwelling on the adjoining lakes some of the well-tasted national fish *skyr*; and as the finale, coffee. A gourmet might possibly have some fault to find with the cookery, but the hungry traveller is not dainty. When, besides these enjoyments, he has the certainty that a bed of down is awaiting him, such as can only be met with in princely palaces, he has everything combined to make him comfortable.—*Winkler's Iceland.*

**USE OF FAT.**—"What is the use of fat?" It performs several offices; one is to round the system and complete the beauty of the person. Your cousin Jane's smooth neck owes its beauty to the skilful manner in which the adipose matter is packed into all the crevices between the muscles, veins and arteries. For nature expends no small amount of labor in the production of beauty. "Behold the lilies of the field; not Solomon in all his glory was arrayed like one of these!" Another use of the adipose matter is to serve as a reservoir of aliment for the support of the system. In the fever which I recently had my stomach was in such a state that it could digest no food, and by one of those beautiful adjustments so common in nature, my appetite rejected it, and I did not eat a mouthful for several days. The consequence was that the heat of the body had to be kept up by burning the fat in the system, and how rapidly this was consumed! I suppose I lost twenty pounds in the course of three days. Hibernating animals, that sleep through the winter, are generally as fat as they can be, when they crawl into their nests in the fall. Their thick furs prevent the radiation of heat, so that little is required to be generated; their breathing and circulation are sluggish, causing a slow consumption of matter, and this matter is supplied by a store of fat in the system, which is slowly burned up during the winter, and the animals come out in the spring as lank as Pharaoh's lean kine. If you put a piece of fat on the fire you will see that it burns with a blaze. Whenever any organic substance burns with a blaze you may be almost sure that it contains hydrogen. The burning of a substance is simply its combination of oxygen. Whenever an organic substance containing hydrogen is sufficiently heated, it is decomposed, and, as the hydrogen is separated from the other elements, it takes the gaseous form. Rising in this hot state, as it comes in contact with the oxygen in the air, it combines with it—in other words, burns; one atom of oxygen combining with one atom of hydrogen, and producing water. There is phosphorus in the bones, which, when separated, will burn with a flame, but, almost invariably, when you see any animal or vegetable

substance burning with a blaze—the flame of a lamp, of a kitchen fire, of a burning building—it is hydrogen in the act of combining with oxygen, producing water. On the other hand, when you see any organic substance burning with a red heat without blaze like charcoal or anthracite coal, it is carbon combining with oxygen, and producing generally, carbonic acid. If the blaze produces a good deal of light, you may be pretty sure that the substance contains both carbon and hydrogen, the light coming principally from the intensely-heated carbon before it is burned.—*New England Farmer.*

**A SARDINIAN FARMHOUSE**—In this court are implements of husbandry, antique enough to tax the ingenuity of Jonathan Oldbuck himself as to their real origin; and in a snug corner are neat rows of cork-pails, there placed in pleasing anticipation of the coming milking time. There is a tremendous baying and rushing forth of enormous boar-hounds, silenced with difficulty by an equally tremendous “Ai ha!” and “Zitto!” from the farmer, where at the noble creatures wag their tails and crouch their several resting-places. And this farmer, with his short kilt of black homespun, wide white cotton drawers and sleeves—so snowy white, too—and loose sheepskin, sleeveless coat, with the shaggy wool outside, neatly-gartered legs, long black beard, and knife-garnished belt—certainly he does not look much like a peaceful tiller of land and tender of flocks; he (to my mind at least) much more resembles a “Capo banditti.” Nevertheless poor Renzo is peaceful and harmless enough, and we may as well follow him into his cheerful and hospitable “stazzu.” The first room is, as usual, the general apartment. The hugh smoking smouldering log occupies the centre; in one corner, neatly rolled up, are the sleeping mats, which at night will be unfurled and placed in a circle round the log, to serve as couches for the younger members of the family; the luxury of beds being reserved for married couples or occasional guests.—*National Magazine.*

**THE SNOW.**—The snow was proverbially called the “poor farmer’s manure” before scientific analysis had shown that it contained a larger per centage of ammonia than rain. The snow serves as a protecting mantle to the tender herbage and the roots of all plants against the fierce blasts and cold of winter. An examination of snow in Siberia showed that when the temperature of the air was seventy-two degrees below zero, the temperature of the snow a little below the surface was twenty nine degrees above zero, over one hundred degrees difference. The snow keeps the earth just below its surface in a condition to take on chemical changes which would not happen if the earth was bare and frozen to a great depth. The snow prevents exhalations from the earth, and is a powerful absorbent, retaining and returning to the earth gases arising from vegetable and animal decomposition. The snow,

though it falls heavily at the door of the poor, and brings death and starvation to the fowls of the air and beasts of the field, is yet of incalculable benefit in a climate like ours, and especially at this time when the deep springs of the earth were failing and the mill streams were refusing their motive powers to the craving appetites of man. If, during the last month, the clouds had dropped rain instead of snow, we might have bored the earth in vain for water; but, with a foot of snow upon the earth and many feet upon the mountains, the hum of the mill-stones and the harsh notes of the saw will soon and long testify to its beneficence. Bridges, earth-works, and the fruits of engineering skill and toil may be swept away, but men will rejoice in the general good and adore the benevolence of Him who orders all things aright. The snow is a great purifier of the atmosphere. The absorbent power of capillary action of snow is like that of a sponge or charcoal. Immediately after the snow has fallen, melt it in a clean vessel and taste it, and you will find immediately evidences of its impurity. Try some a day or two old, and it becomes nauseous, especially in cities. Snow water makes the mouth harsh and dry. It has the same effect upon the skin, and upon the hands and feet produces the painful malady of chilblains. The following easy experiment illustrates beautifully the absorbent property of snow: Take a lump of snow (a piece of snow crust answers well) of three or four inches in length, and hold in the flame of a lamp; not a drop of water will fall from the snow, but the water, as fast as formed, will penetrate or be drawn up into the mass of snow by capillary attraction. It is by virtue of this attraction that the snow purifies the atmosphere by absorbing and retarding its noxious and noisome gases and odors.—*Exchange.*

**AN AUSTRALIAN BANQUET.**—A banquet of a novel character has been held in Melbourne. Some time since an acclimatization society was set on foot by Mr. Edward Wilson, who has effected so much in the way of introducing foreign animals, game, singing birds, &c., into Victoria. This society is now numerous, and has several life members. They have had an experimental dinner, at which were served up many of the native animals, birds, and fishes. The bill of fare comprised kangaroo, wallaby, wombat, bandi-coot, opossum, and porcupine, among the animals; black swan, wild turkey, parouet, water-hens, and wattle-birds, among the fowl; and most of the fish of the Australian seas and fresh waters.

**VITALITY OF SEEDS.**—There is a great difference in the duration of vitality of seeds. Those which have much oil in their composition spoil rapidly, owing to the fatty matter becoming rancid. Seeds of different character, particularly those protected by a shell. Cucumber seeds have been kept good nearly 20 years, corn 30 years, and wheat for more than 1000 years.

## GEORGE LESLIE, NURSERYMAN.

OFFERS FOR SALE, THIS SPRING, A GENERAL assortment of Nursery Stock, consisting of

|                              |     |
|------------------------------|-----|
| Apples, Standard and Dwarfs, |     |
| Cherries, do.                | do. |
| Pears, do.                   | do. |
| Plums, do.                   | do. |
| Peaches, do.                 | do. |
| Appricots and Nectarines,    |     |

## GRAPE VINES,

NATIVE AND FOREIGN.

CURRENTS, GOOSEBERRIES, RASPBERRIES, BLACKBERRIES, STRAWBERRIES, &c., &c.

The collection of fruits cultivated is extensive, and embraces all the different varieties that have been found of value, as well as those of late introduction.

The ornamental department is also extensive, consisting of Shade Trees, Shrubs, Roses, Hardy Herbaceous Plants, &c., &c., with a fine collection of Evergreens.

## LARGE TREES

FOR

### STREET PLANTING,

can be supplied, as also Evergreens, and Deciduous Plants for Hedges.

All the above are of FIRST QUALITY. Packing for a distance carefully performed by experienced hands.

All orders by post or left at the Nursery, will have prompt attention.

Catalogues forwarded gratis on receipt of one cent. stamps.

The stock of Agricultural Seeds is large and well selected. The vitality of each sort is carefully tested, and their genuineness may be fully relied upon. A large stock of Peas, Timothy, and Clover:

Spring Tares,  
" Wheat,  
Black and White Oats.  
Swede Turnips, Purple top.  
" " Green top.  
" " Laing's Improved.  
" " Skirving's Improved.

White Globe Turnip.  
Yellow Aberdeen "  
" Altringham "  
Waite's Eclipse Turnip.  
Stubble or Six Weeks "  
Mangel, Long Red.

" Long Yellow.  
" Yellow Globe.  
" Red Globe.  
" New Olive Shaped.

Sugar Beet.  
Field Peas, several varieties.  
Marrowfats, "  
Barley, two and four rowed.  
Buckwheat.  
Indian Corn, several varieties  
Alsike and White Clover.  
American Orchard Grass,  
Kentucky Blue Grass.  
English Rye Grass.  
French Lucern.  
Cow and Rib Grass.  
Carrot, White Belgian.  
" Long Orange.  
" Altringham.  
Farsnip, Hollow Crowned.  
&c., &c., &c.

Also a full and general assortment of all kinds of Garden Seeds: a Catalogue of which, with directions for sowing, can be had on application. Agricultural Societies ordering Seeds, will be supplied on liberal terms. Country Merchants supplied with complete assortments of Garden Seeds on Commission, neatly put up in boxes of 200 papers each, for retailing at five cents a paper. Also a large assortment of Flower Seeds, embracing the novelties of the season.

No. 126 Yonge Street, Toronto.

March, 1862.

No. 9.

**The Farm—A Chemical Manufactory.**

The proposition that a farm is a chemical manufactory may appear somewhat startling to some of our readers, yet it is nevertheless true. And in proportion as this truth is understood by practical men, will the pursuit of agriculture be advanced, and a higher and more rational interest felt in conducting rural affairs. From the dead earth the farmer raises the living plant, on which subsists the living and moving animal. To comprehend the parts taken by the soil and air respectively in the growth of plants, constitutes the only reliable foundation on which to build a true and enduring system of agriculture. The atmosphere which everywhere surrounds us not only contains the food of plants, but it is the key to the rich storage of nourishment which exists in the soil. As a late writer has observed:—

“The mineral part of the plant—its ashes if it were burned—are as necessary to its growth as the carbon and the water are which it obtains from the air; but this mineral part is locked up in the soil; and unless access be given to the air, there it will remain inaccessible and useless. It is on this fact that the fertilizing influence of tillage depends. Growth, like combustion, is a chemical process depending to a great extent on atmospheric action. Poke the fire and you promote the activity of that chemical action which we call combustion; stir the ground and you promote the activity of the chemical action which we call vegetable growth. If a bit of solid platinum be held in a jet of hydrogen gas it will remain unaffected; if a bit of the same metal in the spongy form, in which an immense increase

is given to the surface of the metal, be held in the same jet, it soon becomes red hot. There is the same kind of difference between a clod of clay and a handful of well-tilled loam as there is between the solid and the spongy platinum; and the great part of the explanation of the fertility conferred by tillage is of the same kind as that which explains the differing relations of the gas to the solid and to the spongy platinum. These relations do indeed differ only in degree. The attractive power of the metallic or of the earthen surface is in proportion to the quantity of that surface. Multiply it by making that spongy, open, porous, which had been solid and impervious, and all the effects due to these attractive powers will be similarly multiplied.

It is this attracting surface in the midst of a soil that enables it to retain its moisture, and to hold, as in a strong box, various manuring substances, as well as the products of their mutual decomposition within it; and which also pulls together into close enough contact the various ingredients of air and soil whose constant chemical action on each other is necessary to fertility. In a well tilled soil every particle is thus wrapped round by food for plants, or by that which is extracting this food from it; so that, while the sub-division of these particles within a given bulk of soil is increasing the quantity of surface yielding food for plants, it is equally efficient in increasing the power of the soil to hold free from waste. It is obvious that this latter power is essential to the economy and the profit of cultivation.

The quantitative character of growth is indeed a truth which ought to be impressed upon the mind. Growth is a real building up of the actual atoms supplied to plant or animals as food. As Mr. Morton has said in one of his Essays in the Journal of the Royal Agricultural Society:—

“Agriculture is an art which by its plants and animals enables us to gather up and assort those

particles in the air and in the soil which, thus assorted and combined, are food for man. Such is the theory, and the practice bears it out; for in reality the farmer does but direct a succession of processes whose effect is to detach these particles from useless positions in the earth, air, and water, and comparatively useless positions in substance of plants, in order with them as material to erect the structure of the ripened crop in one case, and of the fattened animal in the other. His every act of cultivation, by assisting the action of atmospheric solvents, loosens these atoms from previous combinations in the soil—his manuring is a direct addition to them—his draining furthers their more ready transmission to the roots of plants—the hoeing by which he stimulates the growing crop, accelerates their building up into its substance—and all the details of their preparation as food have for their aim the easiest and most economical collection of these particles for the use of man either as vegetable food or as meat on the bodies of fattening animals."

We have already seen that the air is the great storehouse from which the bulk of a plant is derived, and that the value of a manure and the fertility of a soil are owing in great measure to the nature of the mineral food for plants which they respectively contain. We must not think that manuring merely *induces* the extra crop, we know not how. Along with air the manure furnishes the very building material out of which the increased produce is *made*. Those very atoms of nitrogen and phosphorus we are adding in that guano, bone-dust, or farm dung—those very particles of potash or of soda which are detached from the soil by the influences which drainage has brought to bear—those very particles of carbon which our plants, vigorous owing to more thorough cultivation, are extracting from the air in the sunshine, may travel different roads, but they will come to an ultimate residence side by side on the flesh and blood of the fattening animal. The various additions we make to our soil, the fertility we extract from it, may be said to occasion the increased produce of grain and meat which succeeds them, but it is in the same way as the stone and the lime *occasion* the buildings of which they are the very substance and material. Strange as it may seem to those who see the manure continually added to the land and the wheat continually taken from it—the dung-cart going and the harvest-cart returning—a plant has no power to convert one thing into another; it can but take the particles we give it. It will flourish if they are food, it will starve if they are withheld, and if they are poison it will die. There is no mysterious connection between a heavy dressing of dung applied to the land and a heavy crop taken from it: it is not the weight, it is the composition of the dressing that must be considered the measure of its value. The crop finds in the manure the very particles which it needs as building material—drainage and tillage are the

hodmen who bring these building materials to the growing plant—plants are at once the masons who put them together and the erection that is in process of completion—and the whole procedure goes on under the eye and according to the laws of the great Master-Builder who contrived the whole wonderful system of vegetable growth, and conferred the life which puts it in exercise.

It is this way of looking upon the growth of the plants, and indeed of the animals also of the farm, which brings out the resemblance which really exists between the business of the farmer and that of the manufacturing chemist. In both certain materials provided by art and nature are made to act and re-act on one another, with a view to the resultant produce which has a value in the market more than enough to repay all the expenses of the process. The farmer, whether he knows it or not, is truly a chemical manufacturer: he may talk of his plowing, sowing, manuring, cultivating, but the real agents at the bottom of all are those laws of the science of chemistry which regulate the combination of the different substances which he uses, and which out of earth, air, and manure, thus provide food for man and beast. It is a true resemblance which exists between the two professions. The fact that life is an agent in the one case and not in the other does not spoil this resemblance. Life in the one case is but the steam engine in the other—the source of power which lifts and mixes, and fetches and carries; the laws of chemical affinity, which are the real agents in both the cases, prevail in the vessels and tissues of living plants and animals just as they do in coppers and retorts of a chemical manufactory. The comparison between the two is, therefore, *just* as well as instructive.

See now if we cannot learn as much from their contrast. In the one you have an art whose processes are all conducted with the greatest nicety away from the influence of any disturbing cause—whose materials of known composition are weighed with accuracy and mixed in the right proportions—whose agents are applied just in the right degree at the proper time and place—its furnaces may be reduced in intensity, or heated at will seven times hotter. In farming, on the other hand, you have an art the most at the mercy of unmanageable elements, whose processes are exposed to wind and weather, storm and calm, rain and sun, heat and cold, on whose practice there exist the greatest differences of opinion among those engaged in it. Consider, on the one side, varying soil, changeable climate, clumsy implements, uncertain materials, contradictory rules and maxims—this is a picture of our agriculture. On the other side you have every where exact weights and measures, known materials, uniformity of process, and rigid exclusion of disturbing influences.

Notwithstanding the superior ity in all these respects of the chemical manufacture, the manufacturer seeks the aid of science for the superin-

tendence of old plans and guidance into new ones—he sedulously watches, carefully observes, and at once obeys every indication which guides the suggestions of the scientific man for the improvement of his methods.

Notwithstanding his greater need of all possible assistance, the agriculturist, also a chemical manufacturer, is still inclined to look askance and with suspicion on the recommendations of science. We do not think he should recklessly adopt changes of practice except they be preceded by corresponding changes of those circumstances out of which old practice has arisen; but we submit this parallel between the farmer and the manufacturing chemist to the consideration of our agricultural readers, as justifying those among them who are inclined to listen to the criticism of the scientific man upon their practice, and to receive his suggestions for its improvement.

### Plaster with Manure.

County of Carlton, March, 1862.

#### *Editors of Canadian Agriculturist.*

Much more attention is now being paid the making and saving of manure than formerly. I remember when the manure in a neighbouring village was considered useless, no one thought it worth taking away, and it was carted, like other rubbish, to any spot where it might be deposited without creating a nuisance; now it is eagerly sought after, and will be taken away and even paid for.

I have no doubt that many persons, who, like myself, are now for the first time directing their attention to agricultural pursuits, would gladly adopt improved means of increasing the quantity and preserving the quality of this, now much coveted commodity. But unfortunately, if we look for information from our more experienced neighbours or endeavour to obtain it from agricultural periodicals, we find nothing but contradiction, and instead of being instructed are only more bewildered.

At page 62 for 1860, you recommend that the manure heap should be “liberally sprinkled with plaster.” I have for some years past, used the scrapings of the poultry house, with truly astonishing effect on Indian corn; but I find difficulty in keeping it until the proper time, fermentation and escape of ammonia set in as soon as put together. Seeing an article on saving hen-manure by mixing it with plaster and packing away in barrels; I had determined on trying it, when I find that “in a dry state plaster liberates ammonia.” I might go on multiplying instances of like contradictions; but will you inform us under what circumstances plaster may be advantageous, applied to animal excrement.

I am, &c.,

BRIAR.

#### REMARKS.

Hen manure, like the dung of birds in general, comprises both the solid and liquid excrements, and consequently possess the highest fertilising power. In warm and moist weather it readily ferments, and discharges ammonia,—even when treated with sulphate of lime. Manures of this description should be kept in small quantities, or, which is better, mixed with large bulks of light earthy or peaty substances, which would prevent excessive fermentation, and absorb ammoniacal gas. Sulphate of lime, (plaster) has been found beneficial in sprinkling over the floors of byers and stables, and may be advantageously applied to animal excrements, when mixed with earthy and vegetable matters in the form of compost, and to farm-yard manure. Powdered charcoal answers the same purpose in a much higher degree. There is no doubt too much contradiction in the opinions and writings of agriculturists; some of which is inevitable to a pursuit so peculiarly experimental and progressive as that of agriculture. Upon more careful examination, however, much of these anormities will be found more apparent than real; and notwithstanding the obscurity which, to some extent, still surrounds the mode of action of manuring substances, it is gratifying to know that more enlightened attention is constantly being paid by both practical and scientific men to this most important department of improved husbandry.

### Condiments.

Everybody has heard of Thorley and Thorley's Food. Like Holloway, he is everywhere. We cannot travel but we observe his illustrated advertisements, stuck on the walls of every railway station, wherein worn-out Rozinantes are represented, on the one hand, at the last kick, and on the other in full health and vigour, the result, as we are led to suppose, of the use of his wonderful “Condiment.” We can scarcely open a newspaper but “Thorley” stares us in the face; nay, more, like the great Nelson, he has even a Gazette of his own, a special record of his victories over the direful effects of starvation and disease, and a castigating weapon to be laid on the shoulders of all who dare to doubt the infallibility of his life-giving condiment.

Wednesday, the 19th inst., was a great day for Thorley. Under the sponsorship of Mr. Beale Browne, the merits of Thorley's Food was fully discussed at one of the open weekly council meetings of the Royal Agricultural Society of

England, when all the *pros* and *cons* on the subject were fairly brought forward.

The objects which Mr. Beale Browne had in view in introducing the subject of Thorley's food to the consideration of the meeting were, first, to create a friendly discussion upon a matter which he considered important to agriculturists, and, next, to give his own experience regarding it, especially when used in the case of such animals as happen to be in declining condition. He considered scientific men in error when they cried down Thorley's food, and contended that experience proved that it possesses certain fattening qualities. This he illustrated in the following manner:—

"Two or three years ago, through the illness of some of my family, I thought I should give up agriculture and go abroad for some years. I sold off, therefore, my stock of sheep, but I retained a few valuable favorites. I was away for a certain time, and during that time these animals got reduced to a very low ebb. They were, in point of fact, so reduced that about half a dozen of them died. They were broken-mouthed, and some of them had lost their teeth. They were living in a fine piece of clover when I saw them in the spring of the year, and at that time they were a perfect bag of bones, though they were eating oil-cake and corn, which did not seem to improve them in the least. I was very much distressed at the state in which they were, and thinking, at all events, it could not do much harm, if it did no good, I was determined to try Mr. Thorley's food. I therefore wrote to Mr. Thorley to send down a cask of his food, with directions for use. I confess that I was not very sanguine as to the result, because, as I stated before, I was rather prejudiced against it. The food was given with oil-cake and corn, and the animals improved in the most extraordinary degree—so much so, that after they had taken it three or four weeks I really hardly knew them again. When the barrel of food was exhausted I left off Thorley's condiment, and they left off corn and cake and went to grass. They did remarkably well, and the condiment seemed to have entirely renovated the whole constitution of the animals. I saw them about a fortnight ago, when they were in very fine condition for lambing. Some of them had got double lambs, and I must say I should never wish to see ewes in a finer condition than they were in."

Mr. Beale Browne proceeded to argue that the Royal Agricultural Society should consider the matter fairly, not "as dictators to agriculturists generally," but as the "exponents of the wishes and views of the subscribers at large," so that the price of Thorley's food might be reduced, owing to the saving of his immense expenditure in advertising which would follow the official recognition by the society of the value of the condiment. We doubt much if the society will ever take such a step. Thorley is not the only "condiment" manufacturer, and it would be rather too much to expect that the society would place one

manufacturer above all others, simply to allow that man to sell at a reduction of 100 per cent. from his present rates. If Thorley is desirous of securing "a largely increased consumption of his condiment," and to bring it "within the reach of all parties interested in farming operations," which Mr. Beale Browne considered "would be a great advantage," let him at once announce his intention to reduce the price to £18 or £20 per ton, guaranteeing that it shall be as good in point of quality as it is at present, and then let it stand on its own merits; for in such a case, if it is worth the money, it will succeed without any official recognition of it on the part of any Royal Agricultural Society.

In the course of the discussion which followed the reading of Mr. Beale Browne's remarks, it was stated by Mr. Cantrell that he had experienced considerable advantage from giving "condiments," those manufactured by other parties as well as by Thorley, to cart horses out of condition. He gave each horse "rather less than half a pint per day," mixed with damp chaff. Mr. Henry Cotton had also found Thorley's food serviceable in the case of an Irish mare which had suffered severely on her passage to England; he had likewise found it useful in the case of dogs, pigs, and milch cows, improving the latter both in point of flesh and milk. We hope this will form, therefore, the subject of a column in Professor Voelcker's present investigation into the effects of food upon milk.

Mr. Simpson, although "a manufacturer of condiments for cattle," did not attend the meeting for the purpose of advertising his own condiment. At the same time, he contrived to say a few words in its favour, showing that "three years ago he delivered an article, which, in his opinion, was fully equal to Mr. Thorley's, at £18 per ton," further stating that although he has to allow his agents a considerable commission, he can make an article which will give great satisfaction to the consumers at 26s. per cwt., and, as trade increases, "he could make it even at much less than that." A very great reduction, indeed, from the prices at present charged by Mr. Thorley. Mr. Simpson considered, however, that "neither the condiment of Thorley, or that of any body else is superior to linseed" as food for cattle, and that "if we want to rear a calf on skim milk instead of new, use linseed, by all means; but use the condiment in the same way as that in which pepper and salt is used for a beef stack, and sprinkle a little of it over the other food." Mr. Simpson's opinion regarding condiments in general was given in the following terms:—

"Then, again, in regard to the feeding properties of condiment, I don't apprehend that they do, in point of fact, contain any greater amount of feeding properties than could be obtained from good simple food, such as oil-cake. The sole value I attribute to them is the health-giving properties which they undoubtedly possess, and which must depend to a great extent, upon

the proper admixture of the ingredients of which the condiment is formed. That, I believe, is a very important consideration, and is, in my opinion, the only one upon which success or failure depends."

These are all, evidently, honest opinions, coming, as they do, from an interested party, and will have, doubtless, due weight with consumers, leading to a greater consumption of honestly manufactured "condiments" than any amount of elaborate puffing; for, as Mr. Thompson, M. P., and Mr. Barker very properly said, if any prejudice existed against Thorley's food, "it has been created by Mr. Thorley himself, in advertising it at great cost, and, as Mr. Browne says, professing too much." Let the price be such as people can afford; prices in accordance with the intrinsic value of the article; let the professions as to what it will effect be restrained within reasonable limits—prevented, in fact, from trenching on the bounds of quackery, and there is no fear but that condiments will be used whenever it is found advantageous to do so.

Major Munn, like Mr. Beale Browne, was most anxious that all people would understand that he was totally unconnected with Mr. Thorley, did not even know him, had never seen him, and had no personal interest in the success or the failure of his food. But Major Munn thought it right to state that "a great many lambs" of his, "in a very bad condition," affected with "a strong consumptive cough and a small thread-like worm in the air vessels," had been saved—"the whole batch"—by Thorley's food. That another large lot of "refuse lambs, nearly worthless," for which he could not get "more than 6s. or 7s., or, at most, 10s a piece," had all, with the exception of five, "recovered wonderfully," and brought afterwards "45s. to 46s. a piece." That Thorley's food had been most effective in putting some of his old horses in excellent condition; that it had also brought round another horse "that was troubled with worms," even after his career had been nearly brought to a close by means of "a dose of capital stuff" administered to him by the groom; so that he considers Thorley's food "has answered the purpose of a restorative or a medicine," "is a very good ingredient," and he shall, therefore, "continue to use it for horses, cattle, pigs, and dogs."

Mr. Freere—editor of the Society's journal—spoke also in favor of Thorley's food, but "only as valuable for animals that are off their food, and not in a thriving condition," and with his testimony all the array of *pious* in its favor concluded.

The other side of the question was opened by that eminent chemist, Mr. J. B. Lawes, who allowed that "there are certain valuable qualities appertaining to this description of food." It was, however, "entirely a question of medicine," and he had fully satisfied himself that there were tonic properties in the food. Mr.

Lawes referred to his own experiments, the details of which have been given in our columns and concluded by saying that "no science whatever is required to show that those things which tend to stimulate very largely the action of the stomach often occasion a consumption of a larger quantity of food passing through the animal's stomach. But it does not follow that they will make it assimilate, and, therefore, as food, he did not think that these condiments are to be at all recommended. On the other hand, if you give them as medicines, it will, no doubt, be found that they possess considerable medicinal properties which will enable animals to digest food when they would not otherwise be able to do so."

Professor Simmonds followed on the same side; but as his valuable remarks will scarcely bear to be condensed, we shall give them, at full length, in our next impression, and we do so because the learned professor's opinions on all matters relating to the health of animals are most deserving of consideration.

Altogether, the question of condiments has been left very much as it was; unless, indeed, the unanimously expressed opinion of the meeting regarding the excessively high prices charged by Mr. Thorley for his "Food" shall have the effect of inducing him to lower them some 80 or 100 per cent., and thus try the effects of more reasonable prices on the consumption of the article which he manufactures, and in connection with which he has gained so much notoriety.—*Irish Farmer's Gazette*.

### Trees Injured by Mice.

A Correspondent from Haldimand asks, "whether there is any way to prevent Mice from barking young fruit trees, or any cure after they are barked short of setting new ones?"

We know of no better precaution against young fruit trees being injured by Mice during winter than by keeping the ground free of long grass, or any kind of vegetable matter lying thickly around the trees. Open ditches should be kept free of such matters, as they harbour mice in the winter. Treading down the snow after each fall, two or three feet around the tree will be found beneficial, and, if the trees have been mulched in the fall, should never be neglected. If the tree has been deprived of its bark all round, there is no alternative but re-planting. In cases of partial barking, the appl-

cation of the following composition to the wounded part has been found beneficial:—two parts of cow dung intimately mixed with one part each of quick lime and wood ashes. Folding round the stem of the tree pieces of cotton or linen cloth, and smearing the surface with tar as high as the snow is likely to reach, before winter sets in, is often practised with advantageous results.

### On Foliage Plants.

*Read before the Hamilton Horticultural Club, by Thomas Buchanan, Gardener to W. P. McLaren, Esq., of that City.*

MR. PRESIDENT AND GENTLEMEN,—In submitting to your notice a short paper on Foliage Plants, that is, plants with ornamental foliage, I will confine myself to a few, which I think are really acquisitions, wherever a collection of plants is kept, and more especially if there be a conservatory required to be kept gay throughout the year. Every gardener knows the difficulty of keeping such a house furnished with plants in bloom at certain seasons, however large and select his collection of flowering plants may be; but, with a fair collection of foliage plants the task is rendered comparatively light. The most of them are of easy culture and of rapid growth, so that large plants can be grown in a short time. They delight in a warm, moist temperature, and on bright days they require to be shaded from about ten until four, P.M., for a very few bright sunny days would render the beautiful contrasting colours very unsightly of a great many of them. They are greatly benefited by a little liquid manure, for the more rapidly they grow the handsomer they look.

In describing a few of them, I will begin with *Aspidistra Lurida Variegata*,—somewhat after the style of *Arundo Variegata*, but of much stronger growth, with long lanceolate foliage, from four to six inches broad, and from two to three feet long. Some of the leaves are distinctly striped with white, yellow, and orange stripes, on a deep green ground; every leaf is marked distinctly different.

*Alocasia Metalica*,—With rich luscious bronzia leaves, which it retains the whole year.

*Caladium Argyrites*,—An exquisitely beautiful small plant, with small oblong heart-shaped ears, very distinctly marked with blotches of snow white upon a rich green ground. This plant requires a very high temperature to grow it well. It is the gem of caladiums when well grown.

*Caladium Chantini*,—A more robust grower than the preceding, with large oblong heart-shaped leaves on rosea-tinted foot-stems, elegantly

marked with a large crimson centre, and uniformly spotted over with a rosea white, upon a rich green ground; it is a noble-looking plant when it comes to measure about four feet through, with leaves measuring twenty inches long by ten across.

*Caladium Bellymerii*,—Is a less robust grower than *Chantini*, with large oblong heart-shaped leaves, elegantly transversed with silvery veins, on a dark green ground.

*Cissus Discolor*,—The most useful and highly ornamental climbing plant that we have got yet for covering a back wall or a pillar. It is a very rapid grower, and delights in a very moist, warm temperature, rich loamy soil, with frequent applications of liquid manure. After the plant is fairly started it will cover some hundreds of square feet on a back wall, in six or eight months; and, if properly shaded, is truly a magnificent sight. One season is long enough to keep the same plant, as old plants do not do so well. The leaves are oblong, heart-shaped, showing a rich chocolate crimson under side, whilst the upper surface shows a rich purplish ground, with whitish blotches, margined with a crimson hue.

*Begonias* have of late become so numerous that it is no easy matter to know the best, all possessing more or less beauty. Amongst the best are *Begonia Marshalli*, a very striking variety, with very large, slightly angular, macronate, cerrate, cordate, ovate, leaves, very unequal at base, with a large silvery zone, and irregular silvery blotches, between the zone and margin, on a dark rich green ground.

*Begonia Silver Queen*,—Is a smaller grower, with small silvery blotches all over the leaf.

*Begonia Lord Clyde*,—Another small-growing variety, with a silvery zone inside the zone or centre of the leaf, bright crimson, very attractive.

*Begonia President Van Vanden Hecke*, a more robust grower; leaves marked with a silvery zone, and all dotted over as if nicely sanded, on a dark green ground.

*Begonia Pearl*,—A beautiful variety, looks as if set with pearls all over the leaf.

The *Crotons* are a very interesting class of stone shrubs. That most powerful purgative, croton oil, is obtained from the seeds of croton Tiglium.

*Croton Variegata*,—Is a very beautiful shrub, retaining its foliage all the year, with lanceolate leaves, striped with whitish yellow, on a deep green ground.

*Croton Picta*,—Like the preceding in habit, blotches of white, shaded with crimson on a green ground.

*Croton Longifolia*, a smaller growing variety with longer leaves with white blotches on a green ground.

*Cynophyllum Magnificum*,—This noble plant is, without exception, one of the finest

plants yet introduced in its truly magnificent large oblong, ovate leaves. The upper surface is of a remarkably rich deep metallic tinted olive green, which is transversed lengthways by a large prominent silvery gray midrib, and the entire surface is again crossed by the minuter light veins, which diverge horizontally from the centre midrib to the margin.

*Campylobotrys Regalis*.—Leaves of a rich satin green, regularly transversed by silvery nerves, the whole lighted up by a bright metallic lustre and gloss.

*Dracæna Terminalis*.—A beautiful plant; grows to the height of about eight feet, with long lanceolate leaves, beautifully streaked with rose-coloured stripes.

*Dracæna Ferra*.—Resembling the foregoing in habit, with very dark purple, long, lanceolate leaves.

*Dieffenbachia Variegata*.—A rather tall growing plant with lanceolate leaves, irregularly blotched with white on a rich green ground.—This plant looks best when about three feet high.

*Echites putans*.—A very neat climbing plant, with elliptical leaves. Feathery veined with light purple veins—like net-work—in a rich dark greenish purple ground.

*Gesneria Zibrina*.—With gloxinia like leaves, beautifully rayed with very dark purplish rays on a dark green ground, the young leaves look very like a rich velvet.

*Gesneri Donckelaari*.—Contrasts well among other plants, with its almost black foliage.

*Maranta Regalis*.—Is a very neat growing plant, with numerous erect pointed oblong leaves, showing a rich chocolate crimson under surface, whilst the upper surface is of a glossy—very dark green—with bright rosea carmine bonds or lines diverging from the midrib to the margin of the leaf.

*Maranta Zebrina*.—A very distinct and beautiful plant, with long oval acuminate leaves, of a rich shining olive green, beautifully rayed with dark velvety rays.

Among Ferns there are two with ornamental foliage, well worthy of a place in every collection.

*Pteris Argyeria*.—A very robust grower.—Fronds from two to three feet, supported on long foot stems, the fronds are of a deep green, with a broad central stripe of silvery hue down each branch which produces a charming effect.

*Pteris Tricolor*.—A new and very remarkably species, not so vigorous in habit as *Argyeria*, attaining the height of two feet. The fronds are of a deep purple green with a silvery stripe down the centre. The ribs being of a deep red, this combination of colours, with the delicate foliage, produces an effect peculiarly beautiful. This is without doubt one of the best ferns yet introduced. In a collection of foliage plants shown by Mr. Vetch at the Kensington

Gardens, in which Mr. Beaton speaks very highly of the following plants in Mr. Vetch's collection, *Campylobotris Refulgens*, and *Theophrasta Imperialis* as being exquisite, and of *Thurispis dolabrata*, as being the best foliage plant yet sent out. *Pandanis javanicus*, *Folis variegata* and *Pandanis Uvilis*, should be in every select collection however small.

I may at some future time give a few hints as to the growing of some of these named above.

## Seventeenth Annual Exhibition of the Provincial Agricultural Association, to be held at Toronto, 1862.

[The precise days will be announced hereafter.]

## RULES AND REGULATIONS.

### MEMBERSHIP.

1. The members of the Agricultural Societies of the several Townships within the County, or Electoral Division or United Counties, wherein the Annual Exhibition may be held, and the members of the county or Electoral Division Society, shall be also members of the Association for that year, and have members' tickets accordingly; provided the Agricultural Societies of the said Townships, or the Society of the said County or Electoral Division or United Counties, shall devote their whole funds for the year, including the Government Grant, in aid of the Association, and shall pay over the same to the Treasurer of the Association two weeks previous to the Exhibition.

2. The members of the Board of Agriculture, and of the Board of Arts and Manufactures, the Presidents and Vice-Presidents of all lawfully organized County Agricultural Societies, and of all Horticultural Societies, are members of the Agricultural Association for Upper Canada, *ex-officio*. The payment of \$1 and upwards constitutes a person a member of the Association for one year; and \$10 for life, when given for that specific object, and not as a contribution to the local funds.

3. Members can enter articles for competition in every department of the Exhibition, at any time previous to the dates below mentioned, and all who become members previous to or on the Saturday preceding the show will be furnished with tickets admitting them to the grounds during the whole time of the show, without additional charge.

### ENTRIES.

4. No one but a member shall be allowed to compete for prizes except in class, 44, sections 9 to 15 of 47, and 54.

5. All entries must be made on printed forms, which may be obtained of the Secretaries of Agricultural Societies, or of Mechanics' Institutes, free of charge. These forms are to be filled up and signed by the exhibitor, enclosing a dollar for membership, and sent to the Secretary of the Association, Board of Agriculture, Toronto, previous to one of the following named dates:—

6. *Horses, Cattle, Sheep, Swine, Poultry.* Entries in these classes must be made, by forwarding the entry form, as above mentioned, filled up, and member's subscription enclosed, on or before Saturday, five weeks preceding the show.

7. In the classes of Blood Horses and pure bred cattle, full pedigrees, properly certified, must accompany the entry. No animals will be allowed to compete as pure bred, unless they possess regular Stud or Herd Book pedigrees, or satisfactory evidence be produced that they are directly descended from such stock. In the class of Durham cattle particularly, no animal will be entered for competition, unless the pedigree of the same be first inserted in the English or American Herd Book, or in the Upper Canada Stock Register, kept at the office of the Board of Agriculture.

8. *Grain, Field Roots, and other Farm Products, Agricultural Implements, Machinery, and Manufactures generally,* must be entered previous to or on Saturday, three weeks preceding the show.

9. *Horticultural Products, Ladies' Work, the Fine Arts, &c.,* may be entered up to Saturday, one clear week preceding the show.

10. After these dates for the respective classes, no entry will be received. The entry paper and subscription money will be returned to any person forwarding them.

11. In the live stock classes, the entry must in every instance be made in the name of the *bona fide* owner; and unless this rule be observed no premium will be awarded, or if awarded will be withheld.

12. In all the other classes entries must be made in the names of the producers or manufacturers only.

13. In the Agricultural department the competition is open to exhibitors from any part of the world.

14. In the Arts and Manufactures department, no article can be entered for competition unless it be the growth, product, or manufacture of Canada; and no money premium will be awarded except in accordance with this rule; articles of foreign manufacture, however, may be entered for exhibition only, and will be reported upon by the judges, according to their merits, or certificates awarded them, if deserving. Manufacturers are requested to furnish with their articles exhibited, the quantity they can produce, or supply, and the price, for the information of the

Judges; whose division will be based on the combination of quality, style, and price, and the adaptation of the article to the purpose or purposes for which it is intended.

15. No person shall be allowed to enter for exhibition more than one specimen in any section of a class, unless the additional article be of a distinct named variety, or pattern, from the first. This rule not to apply to animals, but to apply to all kinds of grain, vegetable products, fruit, manufactured articles, &c., in which each additional specimen would necessarily be precisely similar to the first.

16. On the entry of each animal or article, a card will be furnished the exhibitor specifying the class, the section and the number of the entry, which card must remain attached to such animal or article during the exhibition.

#### TRANSPORT OF ARTICLES, PLACING THEM ON EXHIBITION, AND CHARGE OF THEM WHILE THERE.

17. All articles for Exhibition must be on the grounds on Monday, of the show week, except live stock, which must be there not later than Tuesday at noon. Exhibitors of machinery and other heavy articles, are requested to have them on the grounds as far as possible during the week preceding the show.

18. Exhibitors must provide for the delivery of their articles upon the show ground.—The Association cannot in any case make provision for their transportation, or be subjected to any expense therefor, either in their delivery at or return from the grounds; all the expenses connected therewith must be provided for by the Exhibitors themselves.

19. Articles not accompanied by their owners may be addressed to the care of the superintendent of the exhibition, who will receive them, on their being delivered at the grounds, but in no case will such articles be brought on the grounds and placed on exhibition, except by and at the expense of the owners or their authorized agents.

20. Exhibitors on arriving with their articles will apply to the superintendent of the grounds, who will be stationed within the entry gate, and will inform them where the articles are to be placed.

21. Exhibitors will at all times give the necessary personal attention to whatever they may have on exhibition, and at the close of the show take entire charge of the same.

22. No articles or stock exhibited will be allowed to be removed from the grounds, till the close of the exhibition, upon the delivery of the President's address, on Friday afternoon, under the penalty of losing the premiums.

23. While the Directors will take every pos-

sible precaution, under the circumstances, to insure the safety of articles sent to the exhibition, yet they wish it to be distinctly understood that the owners must themselves take the risk of exhibiting them; and that should any article be accidentally injured, lost, or stolen, the Directors will give all the assistance in their power towards the recovery of the same, but will not make any payment for the value thereof.

#### STEAMBOATS, RAILROADS, CUSTOMS.

24. The Association will make arrangements with Steamboat and Railroad proprietors for carrying articles and passengers at reduced rates.

25. Arrangements will be made with the Customs department for the free entry of articles for competition.

#### ADMISSION TO THE GROUNDS.

26. Tickets from the Secretary's Office will be furnished each person becoming a member previous to or on Saturday, preceding the Show, which will admit himself only, free to every department of the exhibition, during the Show. Life members admitted free throughout the Exhibition.

27. No members' tickets will be issued after the above last mentioned Saturday evening, but those issued up to that time will be good till the close of the show.

28. Necessary attendants upon stock and articles belonging to exhibitors, will be furnished with admission tickets with their names written upon them, which ticket will be good at the *Exhibitors' Gate only*, during the show.

29. The admission fees to non-members, on Tuesday and Wednesday, will be half-a-dollar, and on Thursday and Friday, a quarter dollar, each time of entering through the gates.

30. Tickets of admission to those who are not members, will be issued on and after Tuesday morning, at 25 cents each,—two such tickets to be given up at the gates each time of admission, on Tuesday and Wednesday, and one such ticket on Thursday and Friday, in accordance with the above rates. Children under fourteen years of age, half-price. Carriages to pay one dollar each admission; each occupant, except the driver, to be also provided with the usual admission ticket. Horsemen half-a-dollar.

#### JUDGES AND THEIR DUTIES.

31. The judges will be appointed by the council of the Association previous to the Exhibition, and will receive a circular informing them of the fact and inviting them to act.

32. The judges are invited to report themselves at the Secretary's office, presenting their circular of appointment, immediately on their arrival at the grounds.

33. The judges will meet, at the committee

room on the grounds, on Tuesday, at 10 o'clock, A. M., to make arrangements for entering upon their duties, and will then be furnished with the committee books containing the numbers of the entries in each class.

34. No person shall act as a judge in any class in which he may be an exhibitor.

35. In addition to the stated premiums offered for articles enumerated in the list, the judges will have the power to award discretionary premiums for such articles, not enumerated, as they may consider worthy, and the Directors will determine the amount of premium.

36. In the Fine Arts and Mechanical Department, Diplomas will be awarded—in addition to the money prizes—to any specimen evincing great skill in its production, or deemed otherwise worthy of such a distinction, on its being recommended by the Judges and approved of by the Committee to whom all such matters shall be referred.

37. In the absence of competition in any of the Classes, or if the Stock or articles exhibited be of inferior quality, the Judges will exercise their discretion as to the value of the premiums they recommend.

38. Each award must be written in a plain careful manner, on the blank page opposite the number of the entry; and the reasons for the award should be stated when convenient.

39. No person will be allowed to interfere with the judges while in the discharge of their duties. *Exhibitors so interfering will forfeit their rights to any premium to which they might otherwise be entitled.*

#### DELEGATES, THE ANNUAL MEETING, &c.

40. Delegates and members of the Press are requested and expected to report themselves at the Secretary's office immediately on their arrival.

41. The Annual Meeting of the Directors of the Association will take place on the grounds on Friday morning, at 10 o'clock.

42. Delegates from County Societies desiring to obtain a portion of the Canada Company Prize Wheat for their Counties, will please apply for it before leaving the exhibition, and take it with them from thence.

#### THE GENERAL SUPERINTENDENT.

43. A General Superintendent will be appointed, who will have the entire supervision of the grounds and the arrangements of the Exhibition. He will have an office upon the ground, where all persons having inquiries to make in relation to the arrangements will apply.

#### PAYING THE PREMIUMS.

44. The Treasurer will be prepared to commence paying the premiums on Saturday,

at 9 a. m., and parties who shall have prizes awarded them are particularly requested to apply for them before leaving Toronto, or leave a written order with some person to receive them, stating the articles for which prizes are claimed.

45. Persons entitled to cash premiums must apply for them at the Secretary's office, who will give *Orders on the Treasurer* for the amount.

46. These orders must be endorsed, as they will be payable to *order*, not to *bearer*, and on presentation to the Treasurer, properly endorsed, will be paid, either in cash, or by cheque on the Bank.

47. Orders for premiums not applied for on Saturday as above will be given by the Secretary, and the amount forwarded by the Treasurer, on receipt of proper instructions.

#### MISCELLANEOUS.

48. Provender will be provided by the Association for live stock at cost price. For information Exhibitors will apply to the Superintendent of the grain and fodder department at his office.

49. An auctioneer will be on the ground after the premiums are announced, for the purpose of selling any animal or article which the owner may wish to dispose of, and every facility will be afforded for the transaction of business.

50. In case the Directors shall require any particular information in reference to animals or articles taking first prizes, the owners will be expected to transmit it when requested to do so.

#### Programme for the Week.

1. **MONDAY** will be devoted to the final receiving of articles for exhibition, and their proper arrangement. None but officers and members of the Association, judges, exhibitors, and necessary attendants will be admitted.

2. **TUESDAY.** The judges will meet in the Committee Room at 10 A. M., and will commence their duties as soon as possible afterwards. As soon as they have made their awards, they will report to the Secretary, and will then be furnished with the prize tickets, which they are requested to place on the proper articles before dispersing. Non-members admitted this day on payment of 50 cents each time.

3. **WEDNESDAY.** The judges of the various classes will complete their awards, and will place all of the prize tickets if possible. Admission this day the same as yesterday.

4. **THURSDAY.** All the remaining prize tickets not yet distributed by the judges will be placed upon the proper articles this morning, before 9 o'clock, if possible. The public will be admitted this day on payment of 25 cents by each person, each time of entering. The amateur bands of music in competition for prizes will play upon the grounds.

5. **FRIDAY.** The annual meeting of the Directors of the Association will take place at 10 A.M., in the Committee Room. The bands will continue to play upon the grounds. The President will deliver the Annual Address at 2 P.M., after which the Exhibition will be considered officially closed, and exhibitors may commence to take away their property. Admission to-day the same as yesterday.

6. **SATURDAY.** The Treasurer will commence paying the premiums at 9 A. M. Exhibitors will remove all their property from the grounds and buildings. The gates will be kept closed as long as necessary, and none will be admitted except those who can show that they have business to attend to.

#### PRIZE LIST.

##### AGRICULTURAL DEPARTMENT.

(COMPETITION OPEN TO THE WORLD.)

##### *Live Stock, Agricultural and Horticultural Products, Implements, &c.*

**MEDALS.**—In all cases the winner of a first prize of \$40 will be entitled to the Association's Gold Medal, value \$40, instead, if he prefer it: and the winner of the first prize of \$20, or upwards will be entitled to the Silver Medal, at \$10, if he prefer it, with the difference in money.

Horses shown as single carriage horses, as saddle horses, or as spans of team or carriage horses, must not be stallions.

No horse will be allowed to compete in more

than one class or section, except when competing for the prize for the best horse of any age in his class, or for the best of any age or blood.

| 4th do.....                             | 1  | 00 |

THE FERGUS CUP.

6. Best grade heifer, not more than two years old on March 1, 1862, the produce of a pure bred Durham Bull, having a recorded pedigree, and of a cow of any breed, not more than one remove from thorough bred. Prize presented by Hon. A. Fergusson. SILVER Cup.
7. Extra Entries

DIPLOMAS will be awarded to the Breeders or Importers of bulls and stallions which take Frist Prizes, when their names and residences are given.

The Judges shall ascertain, in deciding on bull calves in any of the foregoing classes, whether the animal has been suckled or raised by pail, and make allowances accordingly—The exact age of young animals must be stated on the cards, and will be taken into consideration by the Judges in making their awards; and

any person understating the age of an animal will forfeit the premium to which he might otherwise be entitled.

A statement to be produced to show the breeding of animals in class XI.

Young cattle may compete if the exhibitor thinks fit in an older class than that to which they properly belong; but no animal will be allowed to compete in more than one of the foregoing sections, except for the Medals, or where all classes and ages compete together, or in the herds.

Cows in any of the above classes must be giving milk at the time of the exhibition, or be evidently well gone in calf.

An animal will not be allowed to compete as a three-year old cow unless she has had a calf, or is evidently in calf, but a two year old animal having had a calf will be allowed to compete as a two-year old heifer, if the owner thinks fit.

Prizes will be awarded to animals of other breeds than those above mentioned, if deemed worthy.

#### CLASS XII.—FAT AND WORKING CATTLE, ANY BREED.

| Sect.                                                                                                     | \$ | c. |
|-----------------------------------------------------------------------------------------------------------|----|----|
| 1. Best fat ox or steer.....                                                                              | 30 | 00 |
| 2d do.....                                                                                                | 20 | 00 |
| 3d do.....                                                                                                | 12 | 00 |
| 2. Best fat cow or heifer.....                                                                            | 30 | 00 |
| 2d do.....                                                                                                | 20 | 00 |
| 3d do.....                                                                                                | 12 | 00 |
| 3. Best yoke of working oxen.....                                                                         | 20 | 00 |
| 2d do.....                                                                                                | 12 | 00 |
| 3d do.....                                                                                                | 8  | 00 |
| 4. Best yoke 3 years old steers.....                                                                      | 16 | 00 |
| 2d do.....                                                                                                | 10 | 00 |
| 3d do.....                                                                                                | 6  | 00 |
| 5. Best team of oxen, not less than ten yoke from one township, the property of any number of persons.... | 40 | 00 |
| 6. Extra Entries.                                                                                         |    |    |

Prizes the same as in Class XXII.

In the classes of Pigs, the *precise age* of the animal is to be *stated on the cards*.

With a view of encouraging largely the importation of improved stock, the exhibitor of any male animal imported into this Province from Europe since the last Exhibition, which shall take the first prize in any of the above classes, will be paid three times the amount of the premium offered in the list; the exhibitor of any female animal imported from Europe within the same time, taking the first prize, will be paid double the amount offered; the exhibitor of any male animal imported into the Province from any part of America within the same time, taking the first prize, will be paid double the amount of prize offered; and of any female animal imported within the same time, and taking the first prize, one-half addition to the amount of prize offered in the list. Such animals to be the *bona fide* property of persons residing in Upper Canada. Satisfactory evidence must have been given at the time of making the entry that the animal has been imported within the time named, or the increased prize will not be paid.

## CLASS XXVIII.—POULTRY, &amp;c.

| Sect.                               | \$ c. |

| 37. Other entries.....                                                                       |               |

Exhibitors will have to provide their own coops, and are recommended to have them about three feet cube in size, for convenience of arrangement on the grounds.

## AGRICULTURAL PRODUCTIONS.

## CLASS XXIX—GRAINS, SEEDS, &amp;C.

1. The Canada Company's prize for the best 25 bushes of Fall Wheat, the produce of Canada West, being the growth of the year 1862. Each sample must be of one distinct variety, pure and unmixed, of the best quality for seed, and not to be tested merely by weight. The prize to be awarded to the actual grower only of the Wheat, which is to be given up to and become the property of the Association, for distribution to the County Societies for seed ..... \$100 00
- 2nd do by the Association 40 00
- 3rd do ..... 20 00

The winners of the 2nd and 3rd prizes to retain their wheat.

This wheat will be ready for distribution after the annual meeting. The delegates from such County Societies as desire to have a portion are requested to apply for it, and take it with them from the show ground, for immediate sowing, where practicable.

The winners of these prizes will be required to furnish the Secretary with a written statement of the nature of the soil, mode of preparation, the variety and quantity of seed, and time of sowing, manures, (if any used), produce per acre of grain, and any other particulars of practical importance, before being paid the amount of premium. Winners of prizes in the succeeding sections of this class will also be expected to furnish information when applied for

Persons competing for the Canada Company's prize are requested to bring a sample in the straw, pulled from the ground when ripe, with the roots remaining attached.

The Board reserves the right of purchasing part or the whole of first prize samples of grain and seeds at the market value.

| 2d do.....                                                                                             | 6 00   |
| 34. Best Yarn, white and dyed, one pound<br>of each.....                                               | 2 00   |
| 2d do.....                                                                                             | 1 00   |
| 35. Best Yarn, fleecy woollen, for knitt-<br>ing, one pound.....                                       | 2 00   |
| 2d do.....                                                                                             | 1 00   |
| 36. Best Yarn, cotton, two pounds.....                                                                 | 2 00   |
| 2d do.....                                                                                             | 1 00   |
| 37. Extra entries.....                                                                                 |        |

CLASS LIV.—FOREIGN MANUFACTURES.

Foreign articles will be admitted for exhibition only; but Certificates will be awarded to any article of worth or peculiar merit.

MUSIC.

The following prizes are offered for Instru-  
mental Bands:—

|                                                                                                                                                                |         |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| For the Best Canadian Amateur Band<br>consisting of not less than eight per-<br>formers, of whom there shall not be<br>more than two professional artists..... | \$60 00 |
| 2d do.....                                                                                                                                                     | 40 00   |
| 3d do.....                                                                                                                                                     | 20 00   |

Each Band will be required to execute the fol-  
lowing pieces of music, viz:—The National  
Anthem; Rule Britannia; a quick Step; Waltz;  
Song; Polka; Set of Quadrills, and a Medley

or Operatic Piece; and to be on the grounds under the direction of the Committee during the continuance of the Exhibition. Bands intending to compete will communicate their intention to the Secretary of the Association at Toronto, at least a week before the Exhibition commences. The Bands will be required to be on the ground on Thursday and Friday.

### Miscellaneous.

#### Collections of Natural History.

There are few individuals who have not in the course of their lives, met with objects of Natural History which they considered worth preserving; but from the want of knowledge how to proceed to cure or preserve them, have been unable to do so. Indeed many fine specimens have been lost from this cause alone. With no taxidermist near at hand, many a beautiful and rare plumaged bird, or some fine specimen of rare quadrupeds, have been thrown away.

The advantages to be derived from a collection of objects of natural History, are too apparent to require any illustration. And their beauty and variety of plumage and the variety of their forms, have, in a preserved state, ever attracted the admiration of mankind as being next in point of interest to the living animals. Although good drawings and engravings will give us a perfect knowledge of the general appearance of animals, still they are deficient in many particulars, for by them we cannot be made acquainted with the color or the structure of the hair or feathers. The naturalist on all occasions prefers a reference to the stuffed bird to that of a pictorial representation, as by this means he is enabled to trace, compare, and decide on the creature in its several characters and relations. The farmer, the merchant, the lawyer, the mechanic, and the laborer, for it is within the reach of all, can have a Museum or Cabinet of their own, that will enable them, as it were, to look upon the mighty field of nature at one view, with the advantage of having the various classes placed in systematic order, to investigate which in their native wilds would be the business of a life-time. Besides, we can here contemplate without fear the most destructive and furious quadrupeds. Here we can muse upon and study the singularity of organization pointed out by the naturalist.

The collection and preservation of the different insects forms a great addition to the cabinet of the farmer as well as to the entomologist. In this way the farmer can collect the enemies of his crops, and place them in a position where he can muse and study upon their different forms and organization. Minerals and shells, on account of the elegance of their forms and beauty of their colors, should have a place on the shelves of every farmer's cabinet. There is no species in remote countries that does not deserve to be brought home; the things most com-

mon in those countries are frequently rare at home. Upon every farm are some land shells generally little known, which should be picked up when found, and saved. I will in a future number, give some plain directions for preserving insects, skinning and stuffing some of the different birds, &c.

S. P. KEATOR.

#### —Country Gentleman

ITEMPERANCE IN THINKING.—There are other and subtler forms of intemperance. There is intemperance in thinking as well as in drinking as well as in eating, an intemperance which civilisation tends, in some respects, to increase, and which assumes not unfrequently the aspect of a virtue rather than of a vice. It is not the sensual and the grovelling, it is rather the spiritual and the aspiring, that most readily fall into this form of intemperance. The reason is patent on a slight consideration. Labour of the limbs and muscles betrays its effects by obvious exhaustion; but mental labour seems so unlike what is called bodily labour that its bodily instrument—the brain—is forgotten, even if the connection is not, as it too often is, unknown. The thinker, the writer, the speaker, are ignorant or forgetful that the brain with which they work is subject, and in still higher degree, to the same law of frequent alteration of exercise and repose as the rest of the bodily organs. Its very patient endurance is abused, its gentle warnings are unheeded, and too often irreparable injury is sustained before even its beginning is suspected. All professions—the bar, the pulpit, the press; science and literature, politics and commerce, have each its long list of victims to an unenlightened ardour, to an impetuous zeal, not the less to be deplored because its objects are in themselves commonly innocent, or even praiseworthy. In our very universities and schools, before the race of life is well begun the seeds of early decay and of premature debility are too often sown, and in those very youths whose lives are of the utmost value to their race. Such cases we must all of us have seen. But, alas! their example is too often held up for imitation rather than warning; and the mysterious decrees of Providence are too frequently invoked to explain what is but too easily explicable. It has been well said, that if we could with impunity violate the divinely-appointed conditions of our being, there indeed would be a mystery. Perfect health and long life in one student, who adds the night into the day, and habitually disregards the claims of that part of his nature which, because it is the lower, is not the less, but all the more indispensable, would truly be a greater mystery, and even miracle, than the early death of a thousand such. It is earnestly to be wished that the lives of men like Kirke White, and of others nearer our own time that I could name, were re-written, and made to yield a new, wholesome, and much-needed lesson.—*Dr. W. B. Hodgson: "Lectures on the Conditions of Health and Wealth."*

**ANIMALS DESTROYING EACH OTHER**—The instinct of animals to devour each other is well set off by the following lines of the late prime minister, Canning:

"Tell me, tell me, gentle robin,  
What is it that sets thy breast a throbbing?  
Is it that grimalkin, fell,  
Hath killed thy father or thy mother,  
Thy sister or thy brother,  
Or any other?  
Tell me but that,  
And I'll kill the cat.  
But stay, little robin, did you ever spare  
A grub in the ground or a fly in the air?  
No, that you never did, I'll swear.  
So I won't kill the cat,  
That's flat!"

**COVENT-GARDEN MARKET.**—The two great national theaters on one side, a churchyard full of mouldy but undying celebrities on the other, a fringe of houses studded in every part with anecdote and history, a colonnade often more gloomy and deserted than a cathedral aisle, a rich cluster of brown old taverns—one of them filled with the counterfeit presentment of many actors long since silent, who scowl or smile once more from the canvas upon them grandsons of their dead admirers; a something in the air which breathes of old books, old pictures, old painters, and old authors; a place beyond all other places one would choose in which to hear the chimes at midnight; a crystal palace—the representative of the present—which peeps in timidly from a corner upon many things of the past; a wretched bread bank that has been sucked dry by a felonious clerk; a squat building, with a hundred columns and chapel-looking fronts, which always stands knee-deep in baskets, flowers, and scattered vegetables; a common centre into which Nature showers her choicest gifts, and where the kindly fruits of the earth often nearly chooke the narrow thoroughfares; a population that never seems to sleep, and that does all in its power to prevent others sleeping; a place where the very latest suppers and the earliest breakfasts jostle each other on the footways—such is Covent-garden market, with some of its surrounding features.—*Cornhill Magazine* for March.

**THE EYTRICK SHEPHERD'S DOG.**—This dog, though of a sullen disposition, managed a flock with extraordinary skill. On one occasion, about seven hundred lambs, which were under his care at weaning time, broke up at midnight, and scampered of in three divisions across the hills, in spite of all that his master and an assistant lad could do to keep them together. "Sirrah," cried the shepherd in much sorrow, "my man; they're a' awa'." The night was so dark that he could not see his dog; but no sooner did Sirrah hear these words, than he quietly set

off in search of the lambs. The shepherd and the lad did, meanwhile, what they could, and spent the whole night in scouring the country for miles around, but of neither the flock nor the dog could they find a trace. "It was" says Hogg, "the most extraordinary circumstance that had ever occurred in the annals of pastoral life. As day had dawned, we had nothing for it but to return to our master, and tell him we had lost his whole flock of lambs, and knew not what was become of one of them. On our way home, however, we discovered a body of lambs at the bottom of a deep ravine, and the indefatigable Sirrah standing in front of them, looking all around for some relief, but still true to his charge. The sun was then up; and, when we first came in view of them, we concluded it was one of the divisions of the lambs that Sirrah had been unable to manage until he came to that commanding situation.—But what was our astonishment when we discovered by degrees that not one lamb of the whole flock was wanting! How he had got all the divisions collected in the dark is beyond my comprehension. The charge was left entirely to himself from midnight until the rising of the sun; and, if all the shepherds in the forest had been there to have assisted him, they could not have effected it with greater propriety. All that I can further say is, that I never felt so grateful to any creature below the sun as I did to my honest Sirrah that morning."—*Cassell's Popular Natural History.*

**THE COLONIES OF GREAT BRITAIN.**—As the Roman matron said of her children, so may the Sovereign of Great Britain speak of the colonial dependencies of her crown—"These are my jewels!" British India is the Koh-i-noor; Ceylon and Mauritius pearls of great price; Canada a ruby; Australia and British Columbia golden nuggets; the Cape Colony an emerald; and all the other dependencies of the empire brilliants and gems, conferring additional lustre on her diadem. Many a nation of Europe envies us the possession of these numerous colonies spreading over tropical and temperate zones, reaching in the western hemisphere from Vancouver in the north to the Falkland Isles in the south, and in the eastern, from Hong Kong to New Zealand. How little progress have European nations made in colonization compared with ourselves! France has her colonies, few and weak; Russia has hers, military and extensive, but miserable and oppressed. The Portuguese and Danish settlements are scarcely worth mentioning, and those countries have been parting with their possessions rather than extending. Holland still retains her eastern colonies far away from the European seats of Government. But the aggregate of all these colonial possessions is insignificant as compared with those of the United Kingdom.—*London Review.*

**SUBSTITUTE FOR LEATHER.**—Not the least remarkable feature of the present day is the almost universal application of a new discovery, intended, perhaps to supply a want in one particular branch of industry. We are not therefore, surprised to learn that M. Szerelmey, has adapted his process of indurating stone to other substances; and as an instance of this in the Houses of Parliament alone, where its first trial took place, it is used also to prevent rust. Wood, too, is subject to the "Zopissa" process; and last year it was found to act wonderfully on calico, cloth, moleskin, &c., rendering them waterproof, and capable of being worked up into most wonderful imitations of the varieties of dress leather. This last application has recently been patented; and a company is now being formed for the manufacture of boots and shoes, of which the upper leathers are to be made of this new material, which, soft to the foot, adapting itself like a glove, is not liable to crack or shrink, is impervious to wet, and permits the perspiration to pass off. Other improvements, too, in the manufacture itself, are introduced. The sole is divided along the side, leaving the upper portion of it to protect the foot from the rivets; and the hard side of the leather, too, is lowest, leaving the soft side (the "sucker" propensities of which we have doubtless all proved experimentally) to be presented to the foot to absorb its moisture, and not to the ground as is now done. This new material, and the improvements we have mentioned, will, no doubt, recommend themselves, and from the cheapness of the former a great reduction in the price of boots and shoes may be expected.

**ALTITUDE AND DIMENSIONS OF LAKES.**—The great Lake of Titicaca, between Bolivia and Peru, South America, and which is 12,850 feet, or nearly two and a half miles above the level of the sea, is 170 miles in its greatest length and 70 miles in its greatest breadth. Soundings of 120 fathoms have been taken near the shore, and the depth further out is believed to be much greater. The great North American lakes are from 230 feet to 610 feet only above the level of the sea. The Lake of Luzerne, the highest water navigated by steamers in Europe, is 1,406 feet above the sea, and Chautauque Lake, in the the State of New York, and which is the highest lake yet navigated by steam in America, is 1,306 feet above the sea. The Lake of Titicaca would, if the vessels could get there, float all the navies of the world.

**READY WIT.**—The Rev. Dr. McLeod was proceeding from the manse of D—— to church, to open a new place of worship. As he passed slowly and gravely through the crowd gathered about the doors, an elderly man, with the peculiar kind of wig known in that district—bright, smooth, and of reddish brown—accosted him: "Doctor, if you please, I wish to speak

to you." "Well, Duncan," says the venerable Doctor, "can ye not wait till after worship?" "No, Doctor, I must speak to you now, for it is a matter upon my conscience." "Oh, since it is a matter of conscience, tell me what it is; but be brief, Duncan, for time presses." "The matter is this, Doctor. Ye see the clock yonder on the face of the new church? Well, there is no clock really there—nothing but the face of a clock. There is no truth in it, but only once in the twelve hours. Now, it is, in my mind, very wrong, and, quite against my conscience, that there should be a lie on the face of the house of the Lord." "Duncan, I will consider the point. But I am glad to see you looking so well; you are not young now; I remember you for many years; and what a fine head of hair you have still!" "Eh, Doctor, you are joking now; it is long since I have had any hair." "Oh, Duncan, are you going into the house of the Lord with a lie upon your head?" This settled the question; and the Doctor heard no more of the lie on the face of the clock.—*North British Review.*

**REMEDY FOR RING WORM.**—The *North British Agriculturist* says that the disease locally known as ringworm or tetter, which shows itself about the head and neck of young cattle, in the form of whitish dry, scurvy spots, can be removed by rubbing the parts affected with iodine ointment. The disease may also be combated by the use of sulphur and oil; iodine ointment is, however, to be preferred. As this skin disease is easily communicated to the human subject, the person dressing the cattle should wash his hands with soap and hot water after each application of the ointment.

## Editorial Notices, &c.

**THE PROVINCIAL EXHIBITION.**—This number of the *Agriculturist* contains the Prize List for the Provincial Exhibition of this year, although with the dates on which entries are to be made and the Show held, left blank. The Board of Agriculture had fixed upon the week commencing September 29, and ending October 4, for the Exhibition, and the Prize List had been committed to the printer's hands, when it was ascertained that the New York State Agricultural Society had selected the same days for their Show at Rochester. As a great number of persons from each country will be desirous of visiting the Show held in the other, especially when the sites are so contiguous, and would be much disappointed if they were prevented doing so, it is of course

desirable to avoid a clashing of the days, if possible. Some correspondence, therefore, has taken place with the New York Society, having for its object a change of the days of exhibition by one or other of the Societies, so as to avoid a clashing of interests, and the issue of the present number has been delayed some days in the expectation of the decision of the New York Society being ascertained. At the hour of going to press, however, the final conclusion of the Directors of that Society who were to hold a meeting expressly to consider the subject, has not been received, and therefore our Prize List appears, as above stated, with the dates open. If the New York Society agree to change their days then the Upper Canada Show will take place upon the days first fixed upon, viz., Sept. 29 to Oct. 3. If, however, the New York Society determine to adhere to their days, then our Show will be held either one week earlier or one week later, and most probably at the earlier period, viz., on the week commencing the 22nd and ending 27th of September. We shall undoubtedly be able to announce the exact days in our next.

BLACKWOOD'S MAGAZINE, for April: New York, Leonard Scott & Co., 79 Fulton Street.

The contents of the present number of this talented and long established British periodical will be found as usual, exceedingly interesting; they are as follows:—Caxtoniana; a series of Essays on Life, Literature and Morals—part third; The Lives of two Ladies; Political Tragedies in Japan; a Box of Books; Works of Charles Lever; The International Exhibition—its purposes and prospects; Chronicles of Carlingford; Salem Chapel—part third; Spence's American Union.

We gave an extended notice of the American Edition of Blackwood, and the four leading British Reviews in our March number, (page 189) to which we beg again to call the attention of our readers. They contain the cream of British Literature, using that term in its highest and widest acceptance, at a marvellously low price. Mr. Rowsell of this city, and the principal booksellers throughout the British Provinces are agents for these standard works.

### Spring and Summer Horticultural and other Shows.

We are informed of the following Shows to take place this Spring. We request Secretaries of Agricultural Societies to inform us of the date of their Exhibitions at as early a date as possible, so as to admit of publication in time to be of use to those interested.

Hamilton Horticultural Society, 1st Show May 24-

Niagara Electoral Division Society, at Niagara, June 27th.

Kingston Electoral Division Society, Horticultural Show, at Kingston, July 2nd.

### FOR SALE.

A LOT of thorough bred improved Berkshire Pigs of various ages.

R. L. DENISON,  
Dover Court.

Toronto, Aug., 1861.

### Notice of Partnership.

THE Undersigned have entered into Partnership as Seedsmen and dealers in all kinds of Agricultural and Horticultural Implements, under the firm of James Fleming & Co.

JAMES FLEMING,  
GEORGE W. BUCKLAND.

### NOTICE.

JAMES FLEMING & CO., Seedsmen to the Agricultural Association of Upper Canada will carry on the above business, wholesale and Retail, at 126 Yonge-st., 4 doors North of Adelaide-street, until next July, when they will remove to the new Agricultural Hall, at the corner of Queen and Yonge-streets.

JAMES FLEMING will continue the business of Retail Seedsmen and Florist at his old stand, 350 Yonge-street.

Toronto, January 1st, 1861.

### THOROUGH BRED STOCK FOR SALE.

THE SUBSCRIBER has for Sale Durham and Galloway Cattle, male and female. Leicester, Cotswold, and Lincolnshire Sheep, male and female.

January 1, 1862.

JOHN SNELL,  
Edmonton, P. O., C. W.

## GEORGE LESLIE, NURSERYMAN.

OFFERS FOR SALE, THIS SPRING, A  
GENERAL assortment of Nursery Stock,  
consisting of

Apples, Standard and Dwarfs,

## GRAPE VINES,

NATIVE AND FOREIGN.

CURRENTS, GOOSEBERRIES, RASPBERRIES, BLACKBERRIES, STRAWBERRIES, &c., &c.

The collection of fruits cultivated is extensive, and embraces all the different varieties that have been found of value, as well as those of late introduction.

The ornamental department is also extensive, consisting of Shade Trees, Shrubs, Roses, Hardy Herbaceous Plants, &c., &c., with a fine collection of Evergreens.

## LARGE TREES

FOR

### STREET PLANTING,

can be supplied, as also Evergreens, and Deciduous Plants for Hedges.

All the above are of FIRST QUALITY. Packing for a distance carefully performed by experienced hands.

All orders by post or left at the Nursery, will have prompt attention.

Catalogues forwarded gratis on receipt of one cent. stamps.

Address

**Seeds! Seeds!! Seeds!!!**

JOHN GEORGE WAITE

181 High Holborn, London, England.

HAS THE LARGEST STOCK OF VEGETABLE, AGRICULTURAL, and FLOWER SEEDS, IN THE WORLD, and can supply dealers on better terms than any other whole sale house, as he makes most extensive arrangements with none but experienced growers to produce his supply of seeds, which are raised and grown from stock selected under his own personal superintendence, and as they are all cleaned and picked in his own extensive warehouses by an auxiliary strength of several hundred men and women, kept for that purpose, he is enabled to recommend, with the greatest confidence, every description of Seed offered by him for sale, and he therefore invites Seed Dealers to apply for his Catalogue.

TERMS—Cash, or satisfactory reference in England.

March, 1862.

6t.

## Fresh Garden, Field, & Flower Seeds.

FOR SPRING SOWING.

JAMES FLEMING & Co, Seedsmen to the Agricultural Association of Upper Canada, beg to inform their friends, and the Farmers of Canada generally, that their stock of Fresh Seeds is now complete and very extensive, embracing almost every kind of seed suitable for the country. The stock of Agricultural Seeds is large and well selected. The vitality of each sort is carefully tested, and their genuineness may be fully relied upon. A large stock of Peas, Timothy, and Clover:

Spring Tares,

" Wheat,

Black and White Oats.

Swede Turnips, Purple top.

" " Green top.

" " Laing's Improved.

" " Skirving's Improved.

White Globe Turnip.

Yellow Aberdeen "

" Altringham "

Waite's Eclipse Turnip.

Stubble or Six Weeks "

Mangel, Long Red.

" Long Yellow.

" Yellow Globe.

" Red Globe.

" New Olive Shaped.

Sugar Beet.

Field Peas, several varieties

Marrowfats, " "

Barley, two and four rowed.

Buckwheat.

Indian Corn, several varieties

Alsike and White Clover.

American Orchard Grass.

Kentucky Blue Grass.

English Rye Grass.

French Lucern.

Cow and Rib Grass.

Carrot, White Belgian.

" Long Orange.

" Altringham.

Parsnip, Hollow Crowned.

&c., &c., &c.

Also a full and general assortment of all kinds of Garden Seeds: a Catalogue of which, with directions for sowing, can be had on application. Agricultural Societies ordering Seeds, will be supplied on liberal terms. Country Merchants supplied with complete assortments of Garden Seeds on Commission, neatly put up in boxes of 200 papers each, for retailing at five cents a paper. Also a large assortment of Flower Seeds, embracing the novelties of the season.

No. 126 Yonge Street, Toronto.

March, 1862.

4-t.

## VETERINARY SURGEON.

**A**NDREW SMITH, Licentiate of the Edinburgh Veterinary College, and by appointment, Veterinary Surgeon to the Board of Agriculture of Upper Canada, respectfully announces that he has obtained those stables and part of the premises heretofore occupied by John Worthington, Esq., situated corner of Bay and Temperance streets, and which are being fitted up as a *Veterinary Infirmary*.

Medicines for Horses and Cattle always on hand. Horses examined as to soundness, &c.

Veterinary Establishment, Corner of Bay and Temperance Sts.

Toronto, January 22nd, 1862.

## The Imported Thorough-Bred Horse. "Charon"

**W**ILL stand for Mares, at Mr. St George's Farm, Second Concession, and travel as follows, from 1st May: He will leave his own stable on Monday at noon, proceeding down Yonge Street and stopping as required. Will remain at Steele's Tavern all night, will go on to Toronto on Tuesday morning, and stop till Wednesday at noon at Bond's Livery Stables. Will proceed to Weston, and stop there all night; return home on Friday, by Yonge Street; will remain all night at Steele's Tavern, and arrive at his own stable on Saturday morning.

CHARON is by "Archy," by "Camel," by "Whalebone," by "Waxy," by "Pot-s-o's," by "Eclipse," &c, &c. His dam, "Styx," was by "Defence," out of "Proserpine," &c. See Studd Book. Any one acquainted with the English Turf and Stud Book will see that there is not in America a better bred horse than Charon. His pedigree includes the most celebrated sires, and the most fashionable blood of England. Charon was in training for the Derby when he was purchased and brought to Canada. See Ruff's Guide.

TERMS: Season Mares, \$12; Single Leap, \$8; Thorough bred, \$20, and \$12, single leap; Groom's fee, 50 cents.

Mares will be taken into pasture, and carefully attended to on Moderate Terms.

Address H. Q. St. George, Esq, Oakridges Post Office.

Oakridges, April 17, 1862.

## FOR SALE.

**A** LOT of thorough bred Essex Pigs,—bred from recently imported 1st prize animals and who have this season taken premiums at both Township, County, and Provincial Exhibition.

JAMES COWAN.

Cochmor, Galt P. O., Oct. 19, 1861.

**The Swedish Turnip.**

The introduction of the Turnip as a field crop into Great Britain constituted a new and important era in her agricultural history. More sheep and cattle, and those of improved quality were maintained, more manure therefore produced, and, as a consequence, the grain crops received a proportionate increase. The same results have obtained in Canada, wherever turnip and root culture has become established; for as a general rule it will be found that in those districts where the raising of root crops has not yet found its way, cattle in particular, are not only small in number but especially inferior in point of quality.

The whole class of what are designated *Swedish turnips*, are characterised by certain distinctive features and qualities, which broadly distinguish them from the white or common field turnip. The colour of their leaves is invariably of a darker green, almost approaching to blue; the root is also more solid, and possesses a higher specific gravity. They grow more slowly, require better land in higher condition; and are better able than common turnips to resist severe frosts. They contain less water in their composition, and are proportionally more nutritious. They are also more fattening than milk-producing, and less laxative than common turnips. Twenty tons of good Swedes are considered to contain as much nutritive matter as twenty-five tons of the average

of yellow turnips, or as thirty tons of the average of white turnips.

*The common purple top Swede*, is an old variety, hardy, solid, and of good quality, and it has always been regarded as well adapted to the climate and soil of this country. This is probably the parent stock from which others have sprung. It is distinguished from the other "purple tops," by the dull red colour of the upper part of the bulb. It is very solid in texture,

not apt to run to seed, and particularly suited to strong, deep soils. It grows deep in the ground, and the crop consequently appears to the superficial observer to be less than it really is, while the case is reversed with the improved variety. The annexed sketch (fig. 1.) presents a correct view of the shape and appearance of this old and much approved variety.

Mr. Skirving of Liverpool, (England) has distinguished himself in raising new and improved varieties of the Swede; his *Improved Purple Top* has attained to a high reputation, and is more or less cultivated wherever Swedish turnips are grown.

Fig. 2.

ties of Swedes, in consequence of the slight hold it requires of the ground; and in the latter, it swells out on the surface, and when lifted there is not such an adhesion of earth as with the deeper seated roots; a circumstance of great advantage in a wet season.

*Laing's Improved Purple-top Swede.*

(Fig. 3.)

In Lawson's *Agriculturist's Manual* the author says of this turnip, "that it differs from all hitherto known varieties of swedish turnips, in having large cabbage-like leaves, which, by their

horizontal growth, form a thick covering to the soil, thereby materially checking the vigour of autumnal weeds." This peculiarity of shape will be seen in the annexed cut, (fig. 3) where both the leaves and bulb are seen in their natural condition. We have seen excellent crops of this variety raised in Canada, but we question whether for ordinary field culture it is equal to the common or Skirving's Improved Purple-top; certainly it will not yield so large a weight. Of all the class of Swedish turnips *Laing's Improved* is unquestionably the best suited for domestic use. Its size, form and quality admirably adapt it for the table, and it should therefore be preferred by market gardeners to all other sorts of Swedes. *Matson's Swede* somewhat resembles *Laing's* in its mode of growth, being remarkably neat and trim in its appearance; both grow late in the fall, and consequently are not so well adapted to a climate like ours, so peculiarly subject to early autumnal frosts. Both these sorts have been found quite hardy, good keepers, and but little liable to run to seed. This latter circumstance, by the way, greatly depends on purity and change of seed, good cultivation, and the character of the season.—The *Green top Swede* is considered to be one of the oldest varieties, and had formerly a high reputation, which Lawson considers it would have maintained—had the same care been given to its cultivation and the selection of roots grown for seed, as have been devoted to the Purple-tops.

The following table is compiled from the results obtained by the writer of the article on Turnips in *Morton's Cyclopaedia*, in experimenting on the growth of different varieties of Swedes, in 1848. The land on which they were grown is a good black *trap* soil, dry and easy to work. The foregoing crop was oats, after clover and rye-grass cut once and then pastured. The manure for the turnip crop consisted of sixteen double cart-loads of well-rotted compost, (straw, yard dung and rich mud) per acre, and in addition, from four to five bushels of bone-powder were strewed in the drills above the dung. The seed was sown on raised drills, at the rate of 3 lbs. per acre; the young plants all braided well, were thinned about the 30th of June, and the crop raised in the end of October.

## NAME OF VARIETY.

Produce per imperial acre of clean bulbs.

tons. cwt. qrs. lbs

|                                 |    |    |   |    |
|---------------------------------|----|----|---|----|
| Common Purple Top Yellow Swede, | 22 | 11 | 2 | 24 |
| Skirving's Improved do          | 19 | 15 | 0 | 1  |
| Fettercairn Purple Top do       | 18 | 7  | 1 | 8  |
| Laing's do do                   | 14 | 0  | 1 | 5  |
| Common Green Top do             | 21 | 12 | 0 | 16 |
| Fettercairn's do do             | 14 | 16 | 1 | 8  |
| Green Top White Swede           | 14 | 8  | 3 | 18 |
| Purple Top do do                | 16 | 13 | 1 | 13 |

The two latter varieties are described as being of inferior quality, many of these bulbs being principally composed of their roots and matted fibres, and the weights in the table above for these two sorts are probably higher than they should have been, in consequence of the practical difficulty experienced in cutting the roots and fibres away from the bulbs. All the other varieties were of excellent quality.

Although the climate of the British Islands is from its moisture and absence of excessive heat much better adapted to turnip culture than Canada, yet we have seen in this country heavier crops than are indicated in the preceding table. From 800 to 1000 bushels per acre was no uncommon thing to meet with on the farms of those engaged in the turnip competitions that so materially tended to give an impetus to this department of Canadian husbandry during the last few years. A Thorough preparation of the soil, judicious manuring, with a plentiful application of pure seed from proved stocks, and proper after culture, will in general secure a good, paying crop of turnips here as well as in the old country. The root competitions to which we have referred, show indisputably the valuable results which may be obtained in Canada by a vigorous application of the proper means. Our advice is, in turnip and root culture particularly, to attempt no larger a surface than can be managed in the most thorough and perfect manner.

### Flax Culture.

MESSIEURS EDITORS. Is there any way that one of the six Flax Cleaning machines, coming from Belfast to Canada West, could be located in Prince Edward County. Our county is not famed for flax culture, for although I have repeatedly shown samples of flax and seed at our Society Show the judges, (except one trifling 25 cents,) never allowed me any credit for it. I cultivated flax in the North of Ireland for the

Belfast market for twenty years, and knowing the value of the seed for calves raised less or more for the last twenty years in this country for the seed alone. I have never been able to get machinery to clean the fibre; it would not cost over \$60 or \$70 to make the rollers and shaft, with the scutching handles made to be attached to and driven by a horse power of a threshing machine. I am well acquainted with all the processes it has to undergo, except the steaming, which may be preferable to watering, especially in this changeable and extreme climate. The best flax I ever raised in Canada I got nicely watered, and then lost it by three days of warm moist weather. It is more ticklesome to gauge in watering and grassing here than in the North of Ireland, some more to weed and pull, and in an average of years about four inches shorter. These are the drawbacks; but on the other hand the cheapness of the land in Canada may make it as remunerative to grow here as there, and if so, I am sure it will pay better than wheat, if we only get the machinery in operation to dress it well. No one should sow it on new land. It needs to be as near one length as possible, therefore the soil needs to have been thoroughly wrought, moderately rich and clean. My seed has got foul with yellow top, if you can get a barrel of good seed sent to Picton before the first of May, with a good prospect of means of clean fibre, please do so, and oblige,

SAMUEL ANDERSON.

Picton, April 14th, 1862.

[As our correspondent is not far from Kingston he will probably be able to take advantage in some way of the scutching mill placed at that city by the government.—EDS.]

### Cure for Turnip Fly.

No. 1. Recommended by Mr. Fisher Hobbs to the Royal Agricultural Society of England.

Take 1 bushel of fresh white ashes, or Fine wood ashes may be used instead of gas ashes.

1 bushel of fresh lime from the kiln.

6 lbs. of sulphur.

10 do of soot well mixed together, and got to as fine a powder as possible, so that it may adhere to the young plant. The above is sufficient for two acres when drilled at 27 inches, to be applied early in the morning when the dew is on the leaf, with a broadcast machine or sprinkled with the hand carefully over the rows. If the fly continue troublesome the process should be repeated, always when the plant is damp. In light land it is best to make the drills on the flat, the ground being well prepared to receive the seed.

No. 2. Another remedy by the same.

Take 14 lbs of sulphur.

1 bushel of fresh lime.

2 do of road scrapings, or a substance of good

mould where road scrapings cannot be obtained, per acre, mixed together a few days before it is used, applied very early in the morning, or *late* at night; in the same manner as directed in No. 1. using the horse hoe immediately after.

J. B. M.

### Dairy Management, and the Cultivation of Mangel Wurzel.

We take the following abridgment of the proceedings of two important Societies connected with Agriculture in London, from the *Irish Farmers' Gazette* of April 19<sup>th</sup>, and which will be found to contain much useful information of general interest and application.—

Those circles of the agricultural world which have their centre in London had last week a more than usual amount of pleasurable excitement, arising from the discussion of subjects connected with their profession. The ordinary monthly meeting of the Central Farmers' Club took place under the presidency of Mr. Charles Howard, on Monday, the 7<sup>th</sup>, inst., at which Mr. Dumbrell, of Ditchling, Sussex, introduced the subject of "Dairy Management;" and at the weekly meeting of the Royal Agricultural Society, Mr. Freere, Editor of the Society's *Journal*, opened the way for some tolerably useful remarks on the cultivation of mangel wurzel; both very seasonable subjects, and, in the case of the Central Club, possessing furthermore the merit of novelty, nothing immediately relating to it having been previously brought before the club. Professor Voelcker, indeed, as our readers are aware, had recently, at a meeting of the Royal Agricultural Society, expressed his views as a scientific man on the subject, but it remained for the central to pronounce upon its practical bearings.

In doing so, however, it was chiefly the milking properties of certain breeds, and the best manner of feeding milch cows, which were discussed upon; whilst the actual manufacture of dairy products—butter and cheese—was very slightly attended to. Now, in a discussion on dairy management, this was almost like acting the play of Hamlet without the part of Hamlet; for, surely, the manufacture of butter and cheese form a most important part of the circle of subjects which may be comprised under the general head of dairy management. We confess therefore, feeling somewhat disappointed; because, when we found the subject named as one which would be brought forward at a meeting of the Central Club, we hoped to have the pleasure of reading the experience of some practical speakers from the best dairy districts. And, assuredly, the extraordinary difference which exists in the qualities of each of these products of the dairy would have afforded ample room for in-

quiry; some qualities of butter being positive luxuries, whilst others are not good enough to grease a cart wheel; and then there are the rich, mellow English cheeses, which actually melt in the mouth, and, on the other hand, those hard, horny, kinds which might serve as wheels for wheel-barrows, but as an article of food are like the celebrated skim-milk cheese of Suffolk, of which it has been said that it "was so hard, that the pigs grunt at it; dogs bark at it; but neither of them dare bite it."

With reference to the milking properties of the different breeds, Mr. Dumbrell was in favour of the Channel Islands or so called Alderney cow as the best for butter-making, ranking the Ayrshire next, and recommending a cross between these two breeds as producing a very valuable animal. Mr. Little of Wilts, coming from a cheese-making district, advocated the short-horn, believing that "nothing looked better or more promising than a fine herd of short-horns feeding in the open pasture. Mr. Ellis, of Guildford, another short-horn advocate, would "venture to say," in opposition to Mr. Dumbrell's opinion of the Alderneys, "that there were other breeds which, taken as a whole, would be found equal, if not superior, to the Channel Island breed for the purpose under consideration," having "know some cows of the Ayrshire breed which were, in his opinion, more profitable on the whole than the Channel Islands cow." He considered that the first cross between the short-horn and the Channel Islands cow produced a very useful animal for dairy purposes, although, perhaps, it might not "give so much butter as a pure Alderney it was very profitable, arriving early at maturity, and having many good points belonging to the short-horn breed." Mr. Coleman had found that a herd of sixty or seventy Hereford cows did not produce enough of butter and cream to supply the large demand for these articles at Woburn, the Duke of Bedford's seat, where Mr. Coleman is farm manager, and he now keeps a herd of Herefords for breeding or suckling purposes, and another herd, polled Suffolks, on account of their yielding an immense quantity of milk. He had found that crosses between the Hereford and Ayrshire and Hereford and Alderney "improved the feeling qualities of both the Alderney and Ayrshire, while it did not much affect their milking qualities." With respect to the short-horn, he allowed that no breed had a greater tendency to fatten, but in their case "it often happened that the better the pasture the smaller the quantity of milk." Mr. Middleton, Outtleslowe, Oxford, who had kept the best kind of common cows in the midland counties at one time gave his experience of pure short-horns as dairy cows in the following terms:—

"About sixteen or seventeen years ago he considered whether he could not do better by purchasing some pure-bred animals, and then

breeding from them. Accordingly he bought five heifers of Collings' blood (the parent stock of Bates and Booth), and has since bred exclusively from them, and treated them as common cows up to the present day, from time to time purchasing first-class bulls to use with them, and then rearing their calves upon skimmed milk; and he believed that they gave as much milk and butter upon fair treatment as the common cow, but perhaps did not hold it quite so long when they got near calving time. As a set off against that, he sold his bull calves at 6 or 7 guineas, at 10 or 12 days old, and some at a higher figure, to farmers and others; and the result was that he, in conjunction with a few of his neighbours, who have partially adopted this practice, had been the means of improving the breed among the farmers; in fact, the whole of his neighborhood was tolerably well off for good bulls. His own opinion was that the short-horn was not only the best dairy cow, but also after she was dried and barren, the best grazing cow into the bargain, and that the better they are bred the better they feed; and we have Professor Voelcker's experiments in corroboration of the fact that pure-bred short-horns yielded as much milk and butter, within a fraction, as the common cow. In conclusion, he remarked that in advocating the claims of the pure-bred short-horn cow as a dairy cow, he did not intend it as an advertisement, to his herd of short-horns, because they were milkers as well as graziers, but for the simple fact that the Alderneys had been put forward as the best dairy cow; and also to disprove the allegation in the *Mark Lane Express*, a week or two back, that 'pedigree animals are just now getting into bad odour,' because some people will stuff, pamper, and spoil valuable breeding animals for the purpose of exhibition."

This is just such language as we would expect Mr. Tynte, of Tynte Park, to use, were he called upon to speak of the best description of cows for dairy purposes; keeping, as he does, a large herd of high-bred cows solely for the dairy and finding it profitable to do so. In one point, however, we think Mr. Tynte would not agree with Mr. Middleton, namely, that short-horns, perhaps, do not hold their milk quite so long as "the common cows" when near calving time; for the Tynte Park short-horns are not only profitable milkers, but some of the highest bred of the cows, of Booth blood, scarcely ever become dry.

Referring to his system of keeping mich cows, Mr. Dumbrell asked the meeting to forgive him if, on this part of his subject, he should "mount a hobby." His system consists in tethering his cows during summer, instead of allowing them to range over the pasture. The cows are staked down at equal distances, each animal having a range of 16 feet. They are moved frequently, often 12 or fourteen times a day when the grass

is short, only a small portion being given at each time, not more than twelve or eighteen inches, the object being to prevent the cows from placing their feet at any time upon the grass they are about to eat, so as to avoid waste. The cows have water twice a day, and he finds that 8 or 10 statute acres of fair meadow land, pastured in this manner, are generally sufficient "for 25 cows from the time they leave the stall until after haymaking." During summer, when the flies are troublesome, they are tethered only at night, getting rye, vetches, and clover in their stalls under cover during the day. Towards the end of autumn, as the weather becomes cold and wet, the cows must be taken into the stables at night, "lying out in wet weather being detrimental in every way to dairy stock, but no weather," he says, and let our readers in the dairy district mark his words—"no weather is so injurious to the produce of milk, besides being likely to cause abortion or slinking, as white frosts, and the greatest care should be taken that cows in calf should not feed out at that time." Mr. Dumbrell spoke of the merits of the drumhead cabbage as food for milch cows during the early part of winter, being highly nutritious, and assisting the colour of the butter; he follows the use of it with that of swedes, then mangels, spring rape or late sown turnips with rye, bringing the cows on until the grass is ready for a renewal of the tethering system. Of that system he has had 18 years' experience, and although much ridiculed at first, is now adopted by many of his neighbours.—One of these, Mr. Wood, spoke highly in favour of Mr. Dumbrell's mode of tethering cows, stating although at one time he had a very poor opinion of it, experience had made him quite a convert. The other speakers, however, were not inclined to follow his example and become converts to the system, although some of them allowed that it might answer in the case of cows of the Channel Islands breed, which were brought up to it as calves.

Mr. Dumbrell had not found the use of artificial food, such as oil-cake, meal, grains, profitable, but others said they used it regularly, and found that they were paid by the use of it; Mr. Coleman even stating that very few who kept a dairy, "whether of short-horns, Herefords, Alderneys, or any other breed, could supply really good butter without a small portion of one of those articles, viz, cake or meal.

With regard to the indoor management of the dairy, Mr. Dumbrell recommended that a sustained temperature of 56 degrees should be kept up during winter, by means of hot-water pipes; that the milk pans should be of tin, oblong, with rounded corners; that "butter to be perfect should be churned every day," that the cream should not be in a state of decomposition before being churned; that scrupulous cleanliness be attended to in every part of the management;

and that in order to produce good butter there should be a succession of fresh calving cows.

Such were some of the principal points attended to in the course of the evening; but before closing this section of our subject, there were some remarks made both by Mr. Coleman and the chairman which we cannot refrain from giving. Mr. Coleman said "that very few farmers paid people properly to look after the dairy;" that "unless the whole system of a farm were dairying, the work seemed never to be done in a proper manner, and hence it was that the dairy was so much abused and so frequently giving up;" and the chairman, Mr. C. Howard, referring to the great point upon which successful dairy management hinges, said:—

"Speaking as a tenant farmer, he would observe that the successful management of a dairy depended very much upon the ladies of the establishment. They might buy the best cows for milk that they could possibly obtain, and might also feed them with the very best description of food, but if the eye of the mistress was not directed to the dairy, very little good would be accomplished. On his talking over this matter with an old fashioned friend of his some time since, and asking him what system was pursued in his parish, his friend remarked, "There is very little dairying now—we have no dairy ladies." Now, he (the chairman) was at a loss to conceive how it could be beneath any young lady whose lot had been cast in a farmhouse, to notice the dairy. There was no more necessity for her in the dairy than there was for the husband on the farm to perform menial duties; but it was highly desirable that the mistress should have a practical acquaintance with and devote some attention to its management."

We omit the numerous and hearty "Hear, hears" with which these remarks were met; but, whilst they show that dairy farming is an occupation in which determined bachelors should not engage, they also show that a farmer's wife or daughter will never be demeaned in the estimation of sensible people when they take an active part in the management of what is really their particular department. And for the opinion of any other class of people farm-house ladies should not care "two rods of pins."

We now turn to the proceedings at the weekly meeting of the Royal Agricultural Society, where the cultivation of mangel wurzel was discussed. Mr. Freere had made what he termed "a slight experiment" to ascertain the comparative value of "Lawson's artificial guano" and ordinary Peruvian guano as manures for mangel. The season proved unfavourable, and the weight of the crop obtained only ranged from about 15 tons to 22 tons per acre. This "slight experiment" did not, therefore, afford information of any practical value, and the rambling and somewhat incoherent remarks with which he followed up his statement were equally devoid of interest.

Mr. Holland, M.P., was in favour of autumn instead of spring manuring for mangel, evidently referring to the use of long farm-yard dung; and alluded to experiments reported by the late Mr. Pusey, in an early number of the society's *Journal*, when the inference drawn was "that it is more profitable to use some artificial manures in conjunction with dung" in mangel cultivation "than to use either singly."

Mr. Cantrell had grown mangels on the same piece of land four years in succession, giving the land a slight dressing every year, "and every year the roots increased in size." Mr. Peel had grown mangels six years in succession, obtaining good crops all the time, and a friend of his had even "grown mangel on the same piece of land for 17 years in succession, and that land is now being sown with mangel again."

The Chairman, Sir Edward Kerrison, M.P., brought forward reports of two sets of experiments in mangel cultivation, which had been made by his farm bailiff, Mr. Horn, the one in 1856, and the other in 1860; and as those experiments are of considerable practical value, we gave them in full for the benefit of our readers:—

#### EXPERIMENTS IN 1856.

The following experiments were conducted on a poor gravelly soil, in order to ascertain the effects of artificials applied loosely on each. Crop sown the 21st of May, and raised the 12th of November, 1856:—

| No  | Manures per Acre.                                                                                                     | Produce.<br>tons cwt |
|-----|-----------------------------------------------------------------------------------------------------------------------|----------------------|
| 1.  | 20 loads well-prepared stable dung,<br>and 4 cwt. of guano                                                            | 23 16                |
| 2.  | 20 loads well-prepared stable dung,<br>4 cwt. of guano, and 5 cwt.<br>of salt                                         | 30 12                |
| 3.  | 20 loads well-prepared stable dung,<br>1 cwt. of guano, 1 cwt. superphosphate,<br>1 cwt. blood manure and 1 cwt. salt | 25 10                |
| 4.  | 40 loads of dung                                                                                                      | 21 3                 |
| 5.  | 2 cwt. guano, 2 cwt. superphosphate,<br>2 cwt. of blood manure, and 2 cwt. salt                                       | 20 6                 |
| 6.  | 7½ cwt. guano                                                                                                         | 17 17                |
| 7.  | 12 cwt. superphosphate (Lawes')                                                                                       | 14 19                |
| 8.  | 13 cwt. blood manure                                                                                                  | 15 6                 |
| 9.  | 1½ cwt. guano, 1½ cwt. superphosphate,<br>1½ cwt. blood manure, and 1½ cwt. salt                                      | 19 11                |
| 10. | 5 cwt. guano                                                                                                          | 12 15                |
| 11. | 8 cwt. superphosphate                                                                                                 | 11 18                |
| 12. | 8 cwt. blood manure                                                                                                   | 12 11                |

This shows most distinctly, as has been described by different speakers to day, that a combination of farm-yard manure with some species of artificial manure is generally the best method of obtaining the greatest amount of mangel.

## EXPERIMENTS IN 1860.

The following experiments were conducted on the crops of 1860, in order to ascertain which manures raise the greatest weight per acre of mangel, in conjunction with farm-yard dung. Field, a light soil; seed drilled on 27-inch ridges first week in May. Dung applied in the ridges at the time of sowing; the artificials sown by hand over the dung to ensure equal distribution. Crop stored in the second week of October.

| No. | Manure per Acre.                                                                | Produce. |      |
|-----|---------------------------------------------------------------------------------|----------|------|
|     |                                                                                 | tons     | cwt. |
| 1.  | 20 cart-loads of good dung.....                                                 | 16       | 4    |
| 2.  | 20 cart-loads of good dung, 2 cwt. guano, and 4 cwt salt.....                   | 28       | 14   |
| 3.  | 20 cart-loads of dung, 5 cwt. blood and bone manure, and 4 cwt. salt.....       | 24       | 9    |
| 4.  | 20 cart-loads of good dung and 2 cwt. guano.....                                | 21       | 15   |
| 5.  | 20 cart-loads of good dung, 4 cwt. superphosphate, and 4 cwt salt.....          | 22       | 10   |
| 6.  | 20 cart-loads of good dung and 4 cwt. salt.....                                 | 20       | 4    |
| 7.  | 20 cart-loads of good and 4 cwt Lawes's superphosphate.....                     | 18       | 10   |
| 8.  | 20 cart-loads of good dung, 4 cwt. Lawes's superphosphate, and 4 cwt. salt..... | 21       | 10   |

The advantage of using salt in mangel cultivation is clearly shown by these experiments, the application of 4 cwt. or 5 cwt. per statute acre resulting in an addition of from 4 to 7 tons in the weight of the crop. Sir Edward's crops are drilled at 27 inches, but Mr. Peel began with that width, and then got to 30 inches, which he found too small; extending the width, therefore, to 32 and finally to 36 inches, believing that if it is wished to grow roots weighing 16 or 18 lbs. each, they cannot be developed to that size in rows of much less than three feet apart.

Such were some of the principal points brought out in the discussion, and we cannot avoid congratulating the society on the success which has already attended the open weekly meetings. Ample encouragement has been given for persevering in the course recently adopted; for although the peg on which the discussion may hang, as in this case, may not be itself of much value, yet it serves to draw out the results of experience from all parts of the country, and that is of importance.

### Straw as Food.

BY CUTHBERT W. JOHNSON, ESQ., F.R.S.

It is only in modern days that the value of straw has been fairly estimated. As long as our ancestors were content to feed their live stock in yards—that were strictly straw yards—or winter

them in cold impoverished pastures, straw was valued merely as a means of affording a bare subsistence, during the dreary months of winter, to the half-starved inmates of the homesteads. The dung thus produced was of necessity poor, for the days of oil cake had not arrived: artificial food was then rarely thought of: although everything was sold *off* the farm, nothing was returned to it; in fact, if nature, had not helped the farmer in a way he never even suspected, his soil would have been in time utterly exhausted. All that the tiller of our soils then knew was, that when his fields became so impoverished by growing continued crops of the cereals, that these ceased to be remunerative, he had only to leave them for some years to grow a crop of either the self-sown grasses, or those produced by sprinkling the seeds from his hayloft over the land. In this way he used to say that “the land gets *rested*.” He never suspected that, during this resting, as he unmeaningly called it, the soil and the grasses were slowly absorbing from the atmosphere its carbon and its ammonia, and enriching the soil with organic matters, which gradually became sufficient in amount to again support, for a season or two, crops of corn.

When, however, root crops were introduced into the field, and oilcake into our homesteads, then began to be properly appreciated the real use of straw, as a nutritive substance. It is true that the best admixture of these is not always carefully ascertained. A capital lecture on this subject, observes Mr. J. C. Morton, in his valuable edition of “Young Farmers’ Calendar,” was lately given by Mr. Blundell, of Bursledon, before a Hampshire Farmers’ Club. As he truly enough remarked, straw must be more valuable as a feeding material than when used for littering the pens of animals; but to make it so, it must be consumed with roots, oilcake, meal, and other feeding materials. He found that dairy cows in the winter months, if fed on large quantities of roots, particularly mangolds and carrots, refuse to eat straw almost entirely, and become very lean; but they will always eat a full portion of sweet well-harvested straw, when they get a moderate allowance of roots—say, for an ordinary-sized cow, 15lbs. of mangold three times a day, the roots being given whole, just in the state they come from the store heap. Again, calves and yearlings, being fed roots in the same way, will eat a large quantity of straw; and when they have been kept under cover, I have had them in first-rate condition for many years past. Also, fattening beasts, when they get a fair allowance of roots, say 65 to 70 lbs. per day, with from 3 to 4 lbs. of cake or meal in admixture, will then eat straw with great avidity, and do well and profitably. It is however often the case that bullocks receive 100 lbs. or upwards of roots per day, with a large quantity of cake or meal, often 10 or 12 lbs. each per day. They will then not look at straw, and are obliged to be fed with hay. The result of this is, that the cost

price of these quantities and kinds of food is so considerable, that the animals do not yield a profit to their owner.

The amount of straw consumed by stock, and its nutritive properties, have for some time engaged the attention of the Council of the Royal Agricultural Society. In the twenty first volume of its Journal, p. 94, is given the prize essay of Mr. H. Evershed, on the uses of straw on a farm. Its author is of opinion that, although it is a common plan in grazing districts, where roots are scarce, to feed store cattle on about 20 lbs. of straw and 3 lbs. of bean meal, yet that they do better on straw, with roots instead of meal, even when the supply of roots did not exceed  $\frac{1}{2}$  cwt. per head per day. Cattle wintered on straw and meal only become "hide bound," with staring coats. In a note upon this paper Mr. Frere calculates the average production of straw per acre to be  $2\frac{1}{2}$  tons, or 250 tons from 200 acres of corn. He reckons that not more than 4 cwt. of straw enters into the composition of a ton of farm-yard manure; the remainder being, excrements 6 cwt., rain-water 10 cwt. The composition of straw chaff by a cart-horse he places as at least one ton per annum; cattle, 1 ton 1 cwt. per annum; for sheep on a farm of 400 acres he assigns 8 tons of straw-chaff yearly. On an arable farm of 400 acres, therefore, Mr. Evershed calculates that there is required for the fodder of 50 head of large stock, whether horses or beasts, at least 50 tons; for sheep, 8 tons; for storing roots, when wheat is reaped, waste from thatching, making foundation of stacks, &c., say 5 tons; total 63 tons of straw.

As regards the quantity eaten by the stock, Mr. Evershed adds: "It is an interesting fact that well-fed cattle, kept in open yards, will eat more straw during the winter months than other cattle kept under the warm shelter of a roof. The careful manager saves his stock of bean straw until the cold weather sets in, knowing that at that season its bitter flavour will be disregarded. During the winter of 1859-60 I compared the quantity of mixed hay and straw chaff eaten by six oxen, fattened in a warm cattle-house, with that consumed by cattle of the same age and breed in an adjoining yard. Each lot was fed alike in respect of corn and roots, and as much chaff was given as they would eat. Those in the house ate 14 lbs. and the others 18 lbs. daily, showing a difference of nearly a fourth less carbonaceous food, required by cattle when kept in a condition of artificial warmth." In the experiments on fattening cattle at Woburn (*Jour. Roy. Ag. Soc.*, vol. xxii., p. 216), in six experiments, during eight weeks, on 44 oxen, fed in boxes, of an average weight of 1,470 lbs., there was consumed per head weekly about 431 lbs. of cake or corn, 110 $\frac{1}{2}$  lbs. of clover hay chaff, 377 lbs. of roots; in all 531 lbs. of food. There was used besides 133 lbs. of litter. Total feed and litter, 664 lbs. The amount of fresh

dung produced, 575 lbs. The dry substance of the dung was 156 lbs., that of the litter only 106 $\frac{1}{2}$  lbs.: there was therefore a gain of about 50 lbs., or nearly one-half, upon the litter used. The dry substance of the food and litter together was, however, 276 lbs., yielding in dung 156 lbs., or only 56 $\frac{1}{2}$  per cent. of the total; 43 $\frac{1}{2}$  per cent. of the dry substance of the food and litter were therefore either stored up as increase, expended by the animal in respiration, &c., or lost by the decomposition of the manure. To produce 1 ton of fresh box dung, there were consumed 168 lbs. of cake or corn, 431 lbs. of clover-hay chaff, and 1,496 lbs. of Swedes; in all 2,068 lbs. of food, besides 518 lbs. of litter, making a total of 2,586 lbs. of food and litter; this contained 1,075 lbs. of dry substance, and the ton of dung 608 lbs. but we must not fall into the common error of confounding together as food the straw of all kinds of cereals. Neither must we fail to consider the very material difference in value between the straw of the same grass, harvested at different stages of its growth, or in varying degrees of ripeness. These points Professor Voelcker, in his recent valuable paper on the composition and nutritive value of straw, has elaborately examined; as he observes (*Jour. Roy. Ag. Soc.*, vol. xxii., p. 382), "Many farmers form much too low an estimate of the feeding value of every kind of straw, except pea haulm. On the other hand, the views of others respecting the nutriment contained in straw are so unmistakably exaggerated that, with some degree of justice, they are made a laughing stock at the market-table. The main anxiety of the first-named class seemed to be how to tread into manure all the straw grown on the farm; that of the second how to stuff stock with all the straw at their disposal: the creed of the former being that neither little nor much will do their cattle any good, whilst the latter hold that any appropriation of it for litter is an intolerable waste.

"The intelligent agriculturist, however, knows full well that whilst wheat, oat, and barley straw when cut fine into chaff possess a certain feeding value, particularly when this bulky material is combined with some concentrated or more readily digestible food, they are not the less essential on the generality of farms to the production of good farm-yard manure. On most farms, indeed, the want of straw is felt much more on account of the difficulty of preserving the most valuable constituents of the liquid and solid excrements which arises from an insufficient supply of litter, than because an economical substitute of this kind of bulky food cannot be found."

But the professor feels evidently that there is much yet to be learnt with regard to the condition of the straw, the way in which it is produced, and its varying nutritive quality; for he adds, in his opening observations of its chemical com-

position, "As straw contains only from 14 to 17 per cent. of moisture, there is in it about as much solid matter as in meal and other kinds of dry food, although it is considered to be worth only from 20s. to 30s per ton.

"The bulk of straw, however, includes a large proportion of woody fibre, which, if digestible at all, is only partially assimilated in the system. Still, assuming that not more than one-third of the weight of straw is digested by cattle, and probably less by horses and sheep, and granting that the assimilable part is not food of the most nutritious character, straw will still have to be regarded as a more economical feeding material than any other which can be supplied. It is undoubtedly a fact that some practical feeders are in the possession of the secret of converting considerable quantity of straw into beef. What this secret is, perhaps, is not known to themselves. It may be that the combination in which straw is given, or the preparation to which it is submitted before it is placed in the feeding-troughs, has something to do with the success that attends its use; but it is yet more probable that on farms where straw is largely and economically cut into chaff and given to cattle, its condition, from early harvesting and other influences, is better than in other localities where the practice prevails of allowing corn to become over-ripe before it is cut. In consequence of this mischievous practice, straw gets more woody and less digestible than it would have been had the corn crop been cut earlier. Several analyses" of the Professor's, to which I shall presently refer, "show how much the composition and nutritive value of straw depend on the condition in which it is harvested. Indeed, the differences in the composition of somewhat under-ripe and over-ripe wheat or oat straw, are greater than the variations which may be noticed on comparing with each other the composition of wheat, oat, and barley straw. It would appear that in certain districts each variety in its turn becomes superior as food—each kind is preferred and exclusively retained for that purpose; whilst in other districts each is consumed for litter. Moreover, the natural preference shown by stock for one kind or the other affords a practical evidence that the farmer in each case may have a good reason for the choice which suits his locality. We must therefore always expect to meet with great diversity of opinion amongst practical men respecting the nutritive value of wheat, oat, and barley straw. That pea-haulm is too good to be trodden into manure is admitted by all. When properly got in, pea straw is, indeed, a valuable feed substance. With respect to the nutritive properties of bean stalks, again, great diversity of opinion prevails—some considering them almost as nutritious as clover hay, and others only fit for litter."—*Farmer's Magazine*.

(To be concluded in our next.)

## English Agriculture :

AS SEEN BY AN AMERICAN.

We find the following interesting sketch of English agriculture during winter and spring in the Chicago *Prairie Farmer*:

EDS. PRAIRIE FARMER:—The first impression of an American of English agricultural life is exceedingly interesting. No doubt it would be as much and more interesting for an Englishman to look for the first time upon an Illinois prairie in its state of nature, a sea of living green, and to look upon the same scene again in a state of cultivation, upon a field of corn of a thousand acres, inclosed by a pine board fence instead of the English hawthorn hedge.

The thought has occurred to me that I should like, now and then, to give you my impressions of rural and agricultural life in England, as they may first be formed and as I may mature them from after observations and more reliable information. There may be something profitable to be observed from the contrasts. Two such nations as England and the United States cannot thrive within the knowledge of each other, without furnishing profitable lessons from their respective experiences, if they are willing to take lessons in that way. There are certain ideas which each nation, from the nature of their circumstances, must more thoroughly work out; thus England understands better the use of coal and iron, the working of the mines, the art of pottery, &c., because they are within the range of the nation's calling. For the same reason we are ahead of the English in the use of timber, its manufacture from the tree in the forest to the last finish of it in the beautifully constructed house. England knows nothing of our magnificently constructed machinery, such as the saw mills of Saginaw and Green Bay, and the multitudinous inventions for planing and manufacturing of the lumber into doors and sash, mouldings, &c., simply because she has not the timber thus to manufacture. But she has led us in the tubular bridges, crystal palaces, and iron ships, simply because she has the iron and glass, and not the wood.

Thus in agriculture, England has been forced to the highest perfection of science, in the art of production, in order to wrench from the overpopulated soil the capacity to feed the people. The United States must more and more imitate her in this regard, not only to develop our productive capacities, but for the profit of labor as well. It has been the necessity of the case which has made the West call for the reaper and thrasher, and the grain elevating warehouses of Chicago. It was the necessity of the case, high price of labor and great demand for clothing, or the use of the needles, which called for the invention of the sewing machine in America. The low price of labor, the easy supply of the demand of the needle, from the poor women who

could earn their bread only by the interminable stitch, forbade that it should be discovered in England. But all these machines, having been invented and made available with us, are now slowly making their way into England.

It is well for the American to learn what he profitably can from English experience in farming. When we see how fast the capacity of the land in the West is running down, how uncertain almost all our crops are becoming; and when we see over what obstacles of climate, and upon the taxation of its fertility for past ages, with what abundance all crops are raised, and with what certainty they can be relied upon in England—it seems to me our Western farmers can learn these lessons too soon.

There is one fact that should always be remembered when we think of the English farmer—the high price of agricultural products here, and the necessity which compels the English farmer to make the most of his land—and that is, his land rent. Agricultural products are virtually taxed with a land rent, per acre from \$5 \$15 per year. What proportion of cultivators are actual land owners, I am not yet able to state, but I am told that most farmers are land renters, paying to the landlord an amount of rent of from one to three pounds, sometimes much more, according to the available and productive state of the land. Think of a farmer paying for rent, clean cash, as much as will buy him a farm in Illinois, each year! As an encouragement to the idea of the Western farmer sometime having a permanent market for his products in England, he must remember, as an offset to the freight—how much English farm products are encumbered by this enormous ground rent.

Now let me reproduce to the mind of the western Farmer the picture which English cultivation has produced upon my mind, from my first appearance here, the last month in autumn, up to the last in April—agriculture in winter, while in Illinois your ground has been hard with frost or covered with snow. The first surprise is in looking out upon the face of the country at any time in winter, to see grass and vegetation, excepting on the trees, in a perpetual green. This is in a latitude of  $51\frac{1}{2}$  degrees against 42 degrees in Illinois, (the latitude of Chicago,) or nearly 700 miles farther North. Bristol geographically ranges nearly with the latitude of the southern point of Hudson Bay, a locality so far north as to be thought worthless on the Western continent for any agricultural purposes. But on this continent, on an island surrounded by the modifying influences of the seas and oceans, the temperature is so mild that vegetation is in a semi-state of growth the year round.

Farm work is done here all through the winter. January is the great month for grain sowing; February the ground is prepared for root crops; March, the season for young vegetables; and, though this season is wet and backward, the farmers almost despairing, gardens

are blooming in green; the cabbage plants, cauliflowers, and the hundred and one kinds of “greens” making one think of Illinois Junes. The wheat fields are growing, yet badly affected by the wet; the grass is forward, (and oh! how beautifully green the fields look, and about the 15th of April, men were mowing one of the Bristol parks or squares, shearing a fleece of green down about two inches in length. In fields, gardens, and yards about the dwellings of the city, flowers of all hues and degrees of beauty, are putting forth their captivating appeals for admiration. Such is the difference of the state of seasons between the Eastern and Western Continents. I write this letter in the latter part of April; it will be read in Illinois in the latter part of May or first of June, six weeks later; and thus, let the reader fill the picture of contrast in his mind, of what you are then, and what was before us six weeks previously; and what has been the scenery before us the whole winter long. The ground has never frozen hard enough to freeze the turnip tops, or rob the old garden crops of last fall of the green life-like looks.

Perhaps sometime I may paint a picture of the rural scenery of England—and fill in some of the details of farm life, and how they do things here. Such a description may be in season at any time.

A few words as to the present state of farm work, must suffice for this first letter.

The season has been very wet, I am told. I judge so from the fact that it has rained almost every day since the first of December last. One man, boasting of the good weather of January, said they had fourteen fair days in the month, and that was an unparalleled streak of good weather. These fair days have been so unfair to me that I have not observed them. I really have no distant recollection of more than four or five fine days, and they all occurred in April. As the consequence of this wet, the prospect of the crops has been seriously damaged. Work was pretty much stopped on land, since the first of March, to the middle of April. The wheat plant is rank where the land is in a high state, now growing spindling and turning yellow from excessive moisture. In consequence of this, the farm interest took a panic, and the price of wheat came up, in view of the possibility of a failure. But recently there has been a favorable turn, a few of the good days have come; and last Sabbath, our good minister returned devout thanks for the cessation of the rains, and for the sight once more of the smiling sun. But yet, notwithstanding this apparent deluge, as you may think, I have not yet seen one hard rainy day, raining in earnest and done with it, as in America—but we have an excessively wet kind of rains, which will soak everything while it hardly seems to come down in drops.

The whole atmosphere is in a state of suspended superabundant moisture. Some would

say, it is weeping weather. Umbrellas are always in order—and it is a great perplexity to know when to carry them up, or when down. it would suit me better, if the weather was more positive, more rainy when it rains, and more fair when it is fair, which is the American style. But it has just occurred to me, that the weather was not made especially on my account.

Bristol, England, April 19.

### On the Aeration of soil.

By M. JEGER.

M. Daniel Hooibrenk, gardener at Heitzing, near Vienna, announced, in 1859, a new system of culture, stated to ensure a more vigorous growth than can be induced by any other means. This consists in placing in the earth pipes or air channels pierced with holes, which permit the air to penetrate throughout the mass of soil traversed by the roots. According to the inventor of this system, its advantages are numerous and important: he points out the following:

1. The strongest clay soils, under the influence of currents of air transmitted through the pipes, are divided by thousands of small fissures and thus rendered friable, so that roots can easily penetrate them. The depth at which the pipes should be laid depends on the nature and consistency of the soil.

2. After the soil has been aerated by means of the air-pipes, the vegetation of plants growing in it becomes more active, especially in the cases of grain crops and vegetables. The roots finding the soil in a finely divided state penetrate deeper than usual, and are consequently safe from the vicissitudes of temperature which take place near the surface.

3. The looseness produced by the circulation of air in the soil causes a rapid absorption of rain water, and prevents caking of the surface. On the other hand, during long-continued drought, the roots, owing to the great depth to which they have penetrated, are not exposed to the trying effects of the external air, and are enabled to obtain a supply of moisture which they could not do near the surface.

4. The air pipes passing through sour soil causes the sourness to disappear, so that where only bad herbage previously grew, the finer grasses can be produced. These good effects are more particularly observed in swampy or marshy ground, which may thus be changed into fertile soil.

5. The soil, being always kept porous by the circulation of the air, can be more easily worked; and from its openness preventing the accumulation of water, cultivation can be commenced earlier in spring.

6. Plants grown on soil thus improved produce a great mass of roots, and consequently,

being very strong, they require more space. There is no need to sow so thickly as usual; and hence a considerable saving of seed is effected.

7. Manures are much more energetic in their action in soil that is aerated in this way than in that which has not been so treated; the reason of this being, according to M. Hooibrenk, that the aerated soil is more uniformly moist throughout its thickness, and that being the case the decomposition of the fertilising substance is more rapid and uniform.

In short, the inventor of this system states that double and even triple the produce may be obtained from land so treated. This increase soon repays the expense of laying the air pipes. He also states that in the culture of the vine the ripening of the fruit is greatly accelerated, and the quality improved. Such assertions could not fail to be received with doubt by many. Careful experiments were therefore made to test their truth by Messrs. Fitchner & Son.

The field in which these experiments were conducted consists of a bed of loam or sandy clay (*argilosableuse*) from 13 to 16 inches deep, resting on a subsoil of rounded pebble-stones like those in an adjoining brook. On the other side of the field is another brook, about 6½ feet lower. This difference of level, taken in connection with the stony subsoil, made it doubtful at first whether the beneficial action of the air pipes would not be owing to their acting as drains in carrying off surplus water. The field contained rather more than 1½ acre, and had been in cultivation since 1852, but yielded only indifferent returns, at most about six to one of seed. Messrs. Fitchner placed four air pipes at the depth of 3 feet across the field. Their internal diameter was nearly 2½ inches. The field thus prepared was divided into a number of beds, at right angles to the direction of the air pipes, and extending to the portion of ground not furnished with the apparatus. Of the four pipes first laid down, two were joined by a communication pipe, and the mouth of one of them opened into the ash pit of a furnace, whilst the other extremity terminated in an air tank, the sides of which were of masonry.

The surface of ground furnished with air drainage was half an acre and 22 poles. The furnace at the end of the pipe was intended to show that the atmospheric air could reach the fire by passing through the soil. To prove this the opening at the further extremity of the pipe was completely closed, and also the furnace and ash-pit doors, in such a way that no air could reach the fire to support combustion except by passing through the soil under which the pipe leading to the furnace was buried. The fire, however, burned perfectly well throughout the day. To burn ten pounds of wood in 2½ hours would require 8,000 cubic feet of air, and this would have to traverse 108,000 lbs. of soil be-

fore it could reach the furnace. A similar circulation, though less active, must take place whenever there is a difference in the temperature of the air in the drains and that of the atmosphere, and from observations that have been made it has been found that a difference of this kind takes place at least once in 24 hours. M. Jäger remarks that wherever a furnace exists, its fire may be usefully employed in fertilizing by means of air tubes, the adjoining ground; and that gardeners might thus make good use of their hothouse furnaces for improving borders and other parts of their gardens.

The advantageous action of atmospheric air in passing through the soil is due to the fact of its losing a portion of its oxygen, and thus giving rise to the formation of a larger portion of carbonic acid. To determine the changes effected in these respects, Messrs. Fichtner have analysed the air contained in the tubes comparatively with that of the atmosphere. They found, after several days' uninterrupted heating by the furnace, during which time the circulation through the soil had been rapid, the air in the tubes had exactly the same composition as that of the atmosphere (21 per cent. of oxygen, and 79 of nitrogen), and contained in 10,000 parts 12.80 of carbonic acid. Two days after the fire was not kept up the air in the tubes had only 20.85 per cent. of oxygen, and contained 20.99 of carbonic acid in 1000 parts, and from four to six days after the fire was let out, they found 20.71 of oxygen and 35.72 of carbonic acid; six or eight days after, 20.08 per cent. of oxygen, and 35.73 per 1000 of carbonic acid. During these experiments they only found 4 parts of carbonic acid in 1000 of the air in the atmosphere.

The produce of the aerated soil, even taking into account the effect due to the working of the soil in laying the pipes, was considerably increased during the first and only year in which the results are known. A particular increase was observed in the yield of sugar beet. On the estate of Totis in Hungary, where similar experiments have been made, very encouraging results have been obtained. It is, however, impossible as yet to state anything precisely respecting them, and before we can draw conclusions we must wait till the experiments which are being made shall have been carried on for a sufficient length of time.—*Gardeners' Chronicle*.

### Warranty of Soundness in Horses.

The subject of warranty of soundness in horses is one which cannot fail to possess a peculiar interest to those of our readers who, either as agriculturists or sportsmen, are amongst the lovers of horse-flesh. The manner in which horse doctors differ on the important matter of soundness is illustrated at nearly every trial in which the question is involved, and is perhaps

as high an example as can be adduced of the unsatisfactory nature of professional evidence—not less striking even than that of the mad doctors themselves in the celebrated Windham lunacy-case. Mr. Litt, veterinary surgeon, has addressed to the editor of the *Edinburgh Veterinary Review* a long letter on the subject, in which he advocates with considerable boldness and spirit, as the only satisfactory solution of the difficulty, the entire abolition of the law of warranty. We give a few extracts:—

“A rather large experience of more than twenty years, during which I have had some not unfavourable opportunities for observation, has led to the conclusion that, so long as the present most absurd law and custom of warranty exist, so long will the evils that arise from them—the expensive law-suits, the contradictory professional swearing, and the injury and disgust which necessarily follow—continue to exist also. The great aim, then, it appears to me, of everybody who takes an interest in horse-flesh—lawyers excepted, of course—ought to be to seek to bring about the abolition of the law of warranty altogether. Everything that leads in this direction may be recognised as wise and serviceable; and I believe the effect of a thorough inquiry into the various bearings of the subject can scarcely fail to point to this conclusion. Not that I conceive any attempt to amend the law or the operation of the law as it stands much less than Quixotic, but simply because I consider that the more it is investigated, the more clearly will its injustice and its absurdity be made more apparent. Show how injurious is the law itself, and how unwise the custom of warranty, and something may probably be done towards their abolition; for it is in this alone, according to my view of the case, that we can reasonably look for any very manifest advantage to arise. I feel assured that no man having given a warranty is safe from injury. He has made himself amenable to a law, of all laws the most absurd and most unsatisfactory, and he has no right to be surprised if he should chance to reap the natural fruit of such a course. A very worthy man, whom I knew well some years since, a farmer, and at one time a large breeder of horses, understood these things so well, that when he sold a high-priced horse with a warranty he always put the money in the bank, and allowed it to remain six months without reckoning it to his account. If, at the expiration of that time, he heard no complaint of the animal, he then considered himself at liberty to make use of the money, but not sooner. By this means, and by making it a rule to request the immediate return of any horse that had been warranted by him, of which the slightest complaint was made, he managed to steer pretty clear of the law; and though he was once exposed to some annoyance and imposition, I am inclined to think this plan was a wise one, and I recommend all who can afford it,

under the like circumstances, to follow his example. The proverbial uncertainty of the law has unquestionably its highest illustrations in what are called horse causes. Looking back to my own observation and experience of such cases, and speaking necessarily with a peculiar knowledge of their merits, I have no hesitation in saying that the verdicts have been quite as often on the side of *wrong* as on that of *right*, and that, therefore, the law itself is as frequently, in its operation, productive of serious injury as of reasonable justice. This is no extravagant assertion, but a deliberate conviction at which I have been compelled to arrive on a mature consideration of facts. What is more, I always endeavour to force it on any one who may happen to consult me on a question of disputed soundness, and I am inclined to think not without effect; for, though I now examine more horses than I ever did, I have not been engaged in a case of this kind in any court of law for more than a twelve month. To feel that one is in the right is doubtless a very noble and very dignified sensation to entertain at any time; but woe be to the man who is foolish enough to fancy that in an action at law, and when the dispute is about the soundness of a horse, the question of right is likely to have the slightest weight in the decision. I believe he can nurse no greater delusion. For this is undeniable that the law itself is mainly to blame. All definitions of legal unsoundness are vague and imperfect, and admit of endless quibbling and dispute. Veterinary surgeons may differ in opinion; but what then? The authority of all the veterinary surgeons in the world will not weigh a single grain in the balance against the dictum of some famous lawyer, who whatever might have been his attainments in other respects, could have known absolutely nothing about the diseases of a horse."

Mr. Litt then goes on to illustrate his position by some cases in point, which will be better understood by professional than general readers. One of these is as follows:—

"Or take another instance—one of the last cases of the kind with which I have had anything to do. Some of the readers of the *Review* will perhaps remember it as that of *Drury v. Hopwood*. It was tried in London in 1860, and may be briefly explained as involving the much-vexed question of spavin or no spavin. The plaintiff purchased two horses in Liverpool, and took them afterwards to London, where he used them a few weeks without any particular cause of complaint. Being desirous of parting with them, however, they were offered to a dealer, who agreed to purchase them at a given price if Mr. Mavor passed them as sound. They were accordingly examined by Mr. Mavor, who declared them both to be *spavined and lame*, and they were, in consequence, returned to Liverpool. Here they were submitted by the

defendant to the examination of some of the highest veterinary authorities in the place—of Mr. Ellis, Mr. Lucas, and Mr. Bretherton, all of whom were of opinion that they were altogether *free from any appearance of spavin, and that they were quite sound*. Fortified by such opinions as these, the defendant refused to take the horses back, and they were again sent to London. In corroboration of Mr. Mavor's opinion, those of Mr. Field, Mr. Spooner, and Mr. Varnell were also obtained by the plaintiff, and the horses were sold at Tattersall's, and bought back by an agent of the defendant. Shortly afterwards they were again sold, but at different times and to different persons, and *each* at the time of sale examined by a veterinary surgeon, the one by Mr. Payne, of Market Drayton, the other by Mr. Kettle, of the same place, neither of whom, I believe, knew anything of the history of the animals, but both of whom failed to detect any appearance of spavin. Some time afterwards, and shortly before the trial, they were examined also by me, and I may here say emphatically, for myself, that, in my opinion, the hocks of both these horses were perfectly free from any appearance of spavin or any trace of disease of any kind. At the time of trial, one of the horses, then the property of a gentleman of high position in Staffordshire, to whom he had been sold, it may be mentioned, for a larger sum than that given for him originally by the plaintiff, was brought to London, and the coachman who drove him gave evidence to the fact of the horse having been regularly used in his master's carriage, and of his perfect freedom from all sign of lameness. The animal was also brought up for the inspection of the jury themselves. I need not say that the evidence was of the most contradictory character—Mavor, Field, Spooner, and Varnell, on the one side, and Ellis, Lucas, Bretherton, Payne, Kettle, and other less important witnesses, on the other side. Nothing reflecting more seriously on the character of professional evidence can possibly be conceived. The judge—Mr. Justice Erle—summed up rather, I think, in favor of the defendant; for he remarked somewhat pertinently that as the horses had, since they left the plaintiff's possession, been sold for more than he had given for them in the first place, and were shown to be still worth the money, although they had never been subjected to any veterinary treatment, he (the plaintiff) who was suing for damages had suffered no damage, except by his own act of parting with the horses in the particular manner he had done. The jury were locked up a considerable time, but eventually found a verdict for the plaintiff. I must resist any temptation to comment at much length on this case, excepting in so far as it illustrates the absurdity of the law itself. Where such authorities as these differ in professional opinion, could any jury—it may be, of twelve men, not one, of

whom, perhaps, was ever on horseback in his life—be expected to deal out justice? Is justice in such a case not a mere matter of chance, or, perhaps, rather a matter of locality? A London jury naturally attaches more weight to the opinions of men like the professors of the London College and Messrs. Field and Mavor. A jury in Liverpool, or, perhaps, in the provinces, would, I think, have found a different verdict on the same evidence. You yourself may probably think that the weight of authority leans to the witness for the plaintiff; whilst I, on the other hand, may value the sound practical knowledge and varied experience of those of the defendant considerably the highest. "Who shall decide when doctors disagree?" What amount of reasoning can remove the evils, of which this case is only a sample; for many others, quite as bad, may be quoted? I think it must be admitted on all hands that the case is hopeless. The limb (of the law) is terribly, incurably diseased, and there is no remedy excepting in amputation. Try to get rid of it altogether."

The effect of such occurrences as these it will easily be seen must to some extent operate injuriously on the production or first-class horses. The burnt child dreads the fire, and the breeder who has once found himself involved in a horse case will very likely turn his attention in future to stock of a less hazardous description. Mr. Litt does not forget to notice this fact:—

"All this is bad enough, but worse remains to be told. The greatest of all the evils that spring from this condition of the law is undoubtedly the effect produced on the breeding and rearing of first class horses generally. It is not too much to say that many of the largest and best breeders of such animals have been deterred by it from this most important pursuit. I speak only of circumstances within my own knowledge, when I say that it is not easy to estimate the injurious influence of the law of warranty in this direction. Of all the causes that have tended of late years to bring about the scarcity of half-bred horses of the highest quality—for, I think, the fact of this increased and still increasing scarcity will hardly be denied—this is certainly one of the most potent, and it demands, therefore, a more serious consideration, on this account alone, than has hitherto been accorded to it. And, for all this evil to individuals and to the community, what is there in the law of warranty really of compensatory good? You hint that it is chiefly of advantage to the dealer, as affording him too many pretexts for fraudulent attempts to obtain back a portion of the purchase money, and I have myself known more than one instance of the character you relate. There can be no doubt that it does very often serve the purpose of enabling—not dealers only—but many other persons besides—to repudiate a bargain which they have begun to repent. It is idle to speak of it, therefore, as a protection

to the public; for it is the very reverse. They require no such protection. It is sufficient for the law to protect the public against fraud, and men ought to buy horses as they buy other things. If they have not sufficient confidence in their own knowledge of an article they wish to purchase, they ask the opinion, and are guided by the advice, of some one peculiarly qualified to judge of such matters. In the matter of horse-flesh here is a profession, whose members have made this qualification almost a special branch of study. Against false and fraudulent representations on the part of the vendor, be he who he may, let the law be as stringent as you like; but until it ceases to recognize that mischievous thing called a warranty of soundness. I fear there can little good be effected. With these sentiments it will be seen I am not of opinion that it is very important to discuss the question of what ought or ought not to be considered unsoundness in a strictly legal sense. I have had some experience in horse causes, and I have never found much weight attached to veterinary opinions on this subject. As a general rule, I have found that everything of the character of disease, no matter how slight or insignificant, has been held to be an unsoundness, and that to be compelled to admit the slightest deviation from a perfect normal structure of parts was always fatal to any attempt to establish the soundness of an animal."

With such a condition of the law, it is no wonder if often an undeserved amount of odium is made to rest on the shoulders of the examiner. Some of our friends may feel interested to know what one so well qualified to speak as Mr. Litt has to say on this part of the subject:—

"It often happens, however, that the veterinary surgeon—and this is a point that is especially worthy of mention—feels himself compelled, by the absurd state of the law, to give certificates of unsoundness in cases of ailments of so light a character that even he himself scarcely thinks them merited. I was requested a few days ago, for example, to examine, after purchase, a valuable horse, bought by a gentleman in the country for a friend in London. There was, in the inner surface of the head of one of the large metatarsal bones a slight exostosis, quite insulated, as it were, and seemingly unconnected with the hock joint. He was not lame in the slightest, nor likely to be from such a cause. It was the most insignificant thing possible to the eye, and my general rule, in such cases, is to point the thing out to the purchaser, and advise him to take a special warranty in connection with it for a given time. Here, however, I had no such privilege. I was simply asked to give a certificate, and I had no resource but to say "Unsoundness from bone spavin;" for, had I refused to do this, in all probability somebody would have done it when the horse got to London, and the consequence

of my refusal might have been a job for the lawyers. If our employers insist, therefore, upon an absolute *yes* or *no* to the question, 'Is my horse sound in point of law as well as in fact?' it is best for all parties that we should say *no* at once, if there is the very least deviation from a healthy condition; for we can do no greater wrong than to lead them into law. There was a time when I was inclined to stand more firmly by my own views of soundness, in opposition to what I considered unjust and empirical dogmas; but I have had reason to think differently. My opinion that a slightly ragged condition of the frogs, in the hind feet of a mare, was not sufficient cause of unsoundness, on one occasion induced the gentleman who had sold her to defend an action that looked like a mere attempt to repudiate a bargain. The mare had never been lame—at the time of the trial her frogs were sound and firm, although they had undergone no treatment, beyond being kept dry, and a little ragged horn cut away—and my views were supported by several veterinary surgeons of considerable standing; but the authority of Mr. Baron Parke on the subject of thrush was too much for us. Since then I have been especially careful not to differ from such very practical gentlemen as those barons of the law, where there is any danger of a collision, although at other times I prefer to exercise my own opinion, with, I think, rather more of justice to all who may happen to be concerned."

The able editor of the *Veterinary Review* fully endorses Mr. Litt's views. The old Roman law which is still in vogue over the dominions of our most gracious Queen, he reminds us, has been gradually abandoned over the continent of Europe. The French law, for example, regards all palpable defects as necessarily to be seen by the buyer; but if intermittent diseases are discovered, which could not have been observed at the time of the contract being closed, the horse can be returned. This reduces the cases of breach of warranty to a very few, which refer rather to positive frauds than to anything else. "In drawing attention," it is added, "to Mr. Litt's excellent communication, we wish to express a decided conviction that, as the law of warranty stands, no gentleman can submit to its uncertainties and injustices. In signing a deed a person is supposed to understand thoroughly the purport of its contents; but if a contract regarding a horse pronounced sound is signed, it is impossible for non-professional men, and often difficult for a veterinarian, to know if he is subscribing his name to that which may stand the test of a searching enquiry. Admitting that horses should be purchased with the advantage of mature judgment to assist the uninitiated, and that a warranty of soundness must not be relied on, we think it is perfectly proper to retain the law of warranty as far as vice is concerned. Agreeing, therefore, that

the rule *caveat emptor* should be respected, there are many defects such as gibbing, shying, kicking, crib-biting, vicious to shoe or to clean, running away, &c., which might be provided against by warranty, just as much as coloured goods may be warranted fast-coloured. As the opportunities of testing for such vices are very limited in buying, it is expedient to protect the purchaser, at all events until he can have had ample means of trial. There can be few who look upon the warranty of horses as at all advisable or satisfactory; and as the law is certainly very defective, amendment, if not complete demolition, should be insisted upon. It is well known that horse-breeding is rendered so precarious by the practice of warranty as to deter persons from rearing colts. Mr. Litt specially refers to this; and we think our keen sportsmen, who pay so dearly for weight-carrying hunters, and agriculturists, who might profit largely by a safe trade in horses, should lend a helping hand, and insist on better legislation of the subject under notice. If we ask veterinarians to take up the subject warmly we must also instruct the public, and it is to be hoped that the agricultural and sporting press may assist us in framing a new system, as favourable to the farmer as it would be to the public at large.—*Mark Lane Express*.

### Cultivation of the White Bean.

For years we have earnestly advocated the more extensive cultivation of the white bean as a field crop on American Farms.

The great need of American agriculture is a good "fallow crop"—some plant that will stand our hot, dry summers, enrich the soil, and allow the use of the horse hoe to clean the land during its growth. A plant, in short, that shall occupy the same place in our rotation as the turnip does in English agriculture.

The white bean comes nearer to this than any other plant yet introduced. If the beans are consumed on the farm—as turnips always are in England—their cultivation would add materially to its fertility. There can be no doubt on this point. All the leguminous plants—including clover, peas, vetches, beans, etc.—contain large quantities of nitrogen, and this when consumed by animals or plowed under, is converted into ammonia—the very thing which we must need for the growth of the cereals.

Let us then grow beans. No crop will pay better. When prices are good, as at present, they can be sold; and if prices fall, they can be fed out on the farm with advantage.

In regard to their cultivation we have written so much in previous volumes that little need be added at this time. They are generally grown on warm, light soil, but will succeed on almost any soil if properly cultivated. For this, as for

all other crops, the land should be well under-drained, either naturally or artificially. The land may be plowed in the fall and again in the spring, and made clean and mellow before planting; or a clover sod may be turned over, and the beans planted at once. The common "white medium" is generally considered the most productive variety, but the White Mountain or Marrow yields nearly or quite as well, and brings a better price. It is a little larger, rounder, plumper and handsomer, and is gaining in popular esteem.

They may be planted in hills  $2\frac{1}{2}$  feet apart, and 15 to 18 inches apart in the rows, dropping five to six beans in each hill; or they may be drilled in with a machine, in rows  $2\frac{1}{2}$  feet apart, and a single bean 2 inches apart in the rows. The latter, perhaps gives the larger crop, but the former requires less labour in hoeing, etc. In this section they are usually planted the first week in June.—*Genesee Farmer*.

### Benefit of Hogs among Fruit Trees.

The principal object I had in buying the farm I now live, on was the fine orchards of fruit. They were then in a very thrifty condition, loaded year after year, with large crops of fruit; but when we came to picking and packing, we were obliged to throw out large portions of them on account of the worm holes and curculio stings with which they were more or less affected, rendering them unsaleable and fit only for  $\epsilon$  der.

The lower orchard, (the orchards are divided by a public highway,) I have for several years past used as a hog pasture, with very satisfactory results. The apples which were heretofore wormy and knotty, are now as fair, smooth, and free from blemish, as one would wish to see. I allow my hogs and pigs, (the more the better,) free access to the orchards the year round, except a few days in October, while gathering and packing the apples. It is seldom apples fall before they are ripe unless something ails them, and that *something* is usually an apple worm or a curculio, and as the pigs are not very particular about their diet, all goes down with a relish, thereby destroying millions of troublesome insects which could not otherwise be got rid of.

The hogs kept the orchard thoroughly plowed and manured without any assistance from me; kept down the grass and weeds, rendering the orchard much thrifter than could be done with broadcast cultivation, as the hogs do not disturb the roots, but a plow would, besides the inconvenience of working among trees, where you are liable to do more harm than good.

My upper orchard I am obliged to mow, and one would be astonished at the comparative quantity and quality of the fruit in the two orchards. The difference in quantity is as six to one, and the quality 100 per cent,

The pear and cherry trees enclosed in the orchard in which the hogs run, are loaded every year with crops of fruit which would make an amateur's mouth water—while on trees of the same varieties just across the road, can only be found knotty, wormy, unpalatable specimens. Now I can no more afford to be without hogs in my orchard, than I can afford to be without fruit; for without one I should be almost certain to be deprived of the other; and by adopting this course I seldom fail of having a good crop, and *never* fail of finding a ready sale at remunerative prices, even when there is a large crop.

If any of the readers of your excellent journal are skeptical on this point, let them try it for a term of years, and I believe their skepticism will vanish with the increase in their crops.

STOCK FOR CANADA.—The *Helen Douglas*, of Annan, Capt. Maxwell, sailed from Annan Water-foot for Quebec, on Monday last, and had on board the following stock, which has been purchased in this country by Mr. Simon Beattie of Markham, C. W., a native of this place: An entire thorough-bred horse, called Young Irish Bird-catcher, late The Heir, by Grey Plover, son of Irish Bird-catcher—dam by Caronna, out of Repartee; two Short-Horn heifers, and two bull calves, purchased from a good stock near Lesmahagow; 40 Leicester and Lincolnshire sheep selected from one of the best flocks in Lincolnshire; two sows and one boar from Yorkshire and poultry, dogs, &c. The horse was purchased by Mr. Beattie in Ireland.—*Anr<sup>n</sup>* (Scotland) *Observer*.

COMPARATIVE VALUE OF OATS AND ROOTS.  
—Four and two-thirds pounds of oats are estimated by analysis to contain a little over one pound of Flesh, muscle and fat forming principles; to equal that it will take, of carrots, nearly nine lbs.; of Aberdeen turnips, near twenty lbs.; and of Swedish turnips, near seventeen pounds. It will be seen that the difference is greatly in favor of oats.

### Horticultural.

#### The Early Short Horn Carrot.

The early horn carrot is the principal kind used by gardeners on both sides of the Atlantic for early crops; and it is considered the best variety for table use. It possesses a very fine flavour, and commands a ready sale in market. It should be sown early, but we have seen good crops of it produced in Canada in backward seasons like the present, when sown as late as the middle of May. The above cut will afford an idea of the general appearance of this valuable esculent.

For later crops the Altringham and long orange varieties are commonly cultivated; they afford a heavier produce, but are not equal in

firmness of texture and delicacy of flavour to the early horn. Of late years other varieties of early carrots specially adapted to table use have been introduced, but the early horn continues to maintain the precedence. The short yellow, obtained from seed by Mr Vilmorin of Paris, has in Europe a good reputation, and the violet of that seedsman is said to be a large and exceedingly sweet variety, sent to him from Spain.

The long red is usually raised by farmers for feeding stock; but the white or Belgian carrot is now generally cultivated in fields for agricultural purposes, and, when properly managed, yields very heavy crops. For horses in particular, the carrot is excellent.

Carrots of all varieties are easily raised in Canada; they thrive best on a light, rich loam, which should be deeply cultivated; and if farm yard manure is used it should be well decomposed and *thoroughly incorporated* with the whole of the active soil. The seeds have numerous forked hairs on their borders, by which they adhere together, and therefore should, previously to sowing, be rubbed between the hands, and mixed with dry sand in order to separate them as much as possible. The seed being exceedingly light should be sown only in calm weather, carefully covered by the rake, and the surface compressed by a light roller. It is expedient often to test the vitality of the seed previous to sowing, by mixing it with fine sand in a heap, occasionally watering it for two or three weeks; this, however, should be done very early in the season, that germination may only be slightly advanced before finally committing the seed to the earth, otherwise the plant would be weakened. For a bed  $4\frac{1}{2}$  feet by 30 feet, one ounce will be requisite, and the same for 150 feet of drill or row.

#### Grafting Fruit Trees.

An excellent little work on the "*Science and Practice of Gardening*," has just appeared in England from the able pen of Geo. W. Johnson, Esq., one of the highest authorities in Europe on Horticulture. The following is a portion of the author's observations on grafting. We shall again refer to this very useful manual:—

peared in England from the able pen of Geo. W. Johnson, Esq., one of the highest authorities in Europe on Horticulture. The following is a portion of the author's observations on grafting. We shall again refer to this very useful manual:—

for in such case the Green Gage would be altered by its Plum stock, and the *Nonpareil* by its Crab stem. So far from this being the case, the old gardener's maxim—"The graft overruleth the stock quite," in consonance with truth, though it is to be taken with some reservation. The graft prevails and retains its qualities; yet the stock has the power of influencing its productiveness as well as the quality of the fruit. Thus, a tree having an expansive foliage and robust growth, indicative of large sap vessels and vigorous circulation, should never be grafted upon a stock oppositely characterised, for the supply of sap will not be sufficient: illustrations are afforded by the *Codlin* never succeeding so well on a Crab, nor a *Bigarreau* on a wild Cherry, as they do on freer-growing stocks. Indeed, we have no doubt that every tree and shrub succeeds best, is most productive, and most free from disease, if it be supplied with sap from roots and through a stem of its own peculiar kind. This is evident to common sense; nor would any scion be grafted upon a stock of another species or variety, if it were not that such stocks are most easily obtainable, or for producing some alteration in the habit of the plant, or to fit it for some particular soil.—For example, our choicest Cherries are grafted or budded upon the wild Cherry only because of its being easily obtained; and every one must have noticed the frequently occurring consequence, an enlargement, appearing like a wen, encircling the tree just above where the graft and the stock joined—the growth of the former having far outstripped that of the latter. But the stock has some other influence over the sap, besides limiting the quantity of sap supplied to the scion, an influence not only arising from the size of its vessels, but from its susceptibility to heat. It has a further influence over the scion by the sap becoming more rich, indicated by its acquiring a greater specific gravity in some stocks than in others, during its upward progress. The specific gravity of the sap of a *Black Cluster* Vine stock on which a *Black Hamburg* had been grafted was, when obtained six inches from the ground, 1.003, and at five feet from the ground 1.006; but the same *Black Hamburg*, growing upon its own roots, had specific gravities at corresponding heights of 1.004 and 1.009. This increase is of great importance to a tree's growth when the quantity of sap passing annually through its vessels is considered. The

exact amount of this it is perhaps impossible to discover, but its extent may be appreciated by the quantity of moisture their roots are known to imbibe, and by the facts that a small Vine-branch has poured out 16 ozs. of sap in twenty-four hours; a Birch tree a quantity equal to its own weight during the bleaching season; and a moderate-sized Maple about 200 pints during the same period."

### Culture of Melons.

It is a great object to get melons early. This cool, richest and most luscious of all herbaceous fruits, to be fully appreciated, should be eaten in the hot weather of July, August and early September. They may be started in the hot-bed, provided some means be contrived by which they may be lifted and transplanted to open ground without disturbing the roots. Some plant over a piece of turf in the hot-bed, which may be carried with the plants to the open ground; others, in small open baskets, which may be set with the plants in the hill, the roots being able to push through the interstices in the basket; and others again in a shell made by excavating a large turnip, which soon rots in the ground or may be removed after the plants are carried to the hill. In this climate, however, it is easy, with a little care, to raise melons sufficiently early in the open ground.

A light, rich, sandy soil should be selected. In the lack of such a soil, it will be well to supply a bushel or two of sand to each hill. The soil should be deeply dug, thoroughly pulverized and enriched. A little finely pulverized chicken or pigeon manure, mixed with the soil of each hill, will be found an excellent stimulant. A frame, a few inches high, around each hill, may be covered with glass or mosquito netting, and will be a great protection to the plants from cold winds, frost, or the striped bugs. Eight or ten seeds should be planted in each hill, and after they are safe from insects, should be thinned out to two or three.

The greatest difficulty in point of success in melon raising, is in obtaining and preserving the seed pure. The varieties of the melon readily mix with each other, and if you save your own seed, without great care, you will soon have no good melons.

The fruit, the first year will not show the mixture; the second year it will be quite apparent, and the third year may be worthless. To preserve the seed pure, it is not safe to plant nearer than ten rods of any variety with which they can mix. When you have planted a good variety where it is safe from admixture, save seed enough to last five years. Melon seed improves with age up to five or six years.—*Valley Farmer*.

## The Dairy.

*From the Ohio Farmer.*

### How to make Cheese.

I have been a cheese-maker for fifteen years, and I thought that at the opening of this year I would give the readers of the Ohio Farmer the benefit of my experience in cheese-making. The first thing necessary to success in cheese-making is

#### *A Good Grass Farm,*

Where timothy, red-top, clover, and other tame grasses abound, instead of the harsh, coarse, wild grasses. These latter will not yield the quantity nor quality of milk that dairymen want. But this is well settled and admitted.

#### *Good Cheese Houses.*

After the grass and comfortable houses for stock and tenants, come convenient and comfortable cheese-houses for making and curing the cheese. These save much unnecessary labor.

#### *Good Cows.*

There cannot be too much care in selecting cows for the dairy, as one good cow is worth two poor ones.

#### *Milking.*

Almost every one can milk, yet there is no part of cheese-making done with less care and attention than this, nor is there any part which ought to be done with greater care and precision than milking. It is usually done (in this country) in a muddy yard, and at very irregular periods; sometimes before light in the morning; sometimes after dark at night; sometimes at 9 o'clock in the morning, or 4 in the afternoon; sometimes by one milker and then by another; this, in my judgment is all wrong. The cows should be driven to the barn at regular hours, morning and evening; they should all be put into the stables and milked by the same person every time; don't change milkers, but have steady milkers for the same cows. A cow should not only be milked by the same person, and at the same hour, but she should be milked in the same time. In order to do this, there should be no noise, or talk, or play, among the milkers. I cannot urge this caution too strongly—upon it depend the profits of cheese-making.

#### *How long should Cows be kept from pasture.*

Not over one and a-half to two hours. Most of this time is necessarily consumed in driving to and from the pasture, and in milking. Thus from three to four hours each day of the cow's best time for grazing is used up. The rule is, to be as expeditious as possible; upon it depends the success of cheese-making.

#### *Scrupulous Cleanliness.*

Should be observed in everything about the

dairy-house, milk-pails, place of straining milk, whether in the vat or elsewhere. All dirt, mud or standing water around or near the place of making cheese should be removed, and none permitted to stay in the presence or near the place of keeping milk or making cheese. There is not known to me any production, animal or vegetable, so sensible to impressions from surrounding circumstances as milk, cream, and butter; hence arises the necessity of keeping everything around the dairy as sweet and clean as possible. No person who lies in bed until his evening milk sours, or who is not careful about his milk, can possibly make cheese of the first quality. Very much more ought to be said upon this part of the subject, and very much more attention ought to be given to it by nearly every one of our dairymen. Next in order comes

#### *Preparing milk to receive the Rennet.*

This is done in ways almost without number, with very nearly the same result. All kinds of vats are used, like all kinds of cooking-stoves and mowing machines, every one thinking his own the best. I have always used the one made by Jameston & Co., of Warren, Trumbull county, Ohio, and like it very well, (perhaps it is not the best.) We strain our evening's milk into this vat, and manage, by using cold water, to extract the animal heat from the milk as soon as possible, in order to have it retain its sweetness until morning and to obstruct the rising of the cream. In the morning, what cream does rise is removed, and the morning's strained into the vat with the evening's milk, which cools the whole together, when a fire is started in the furnace of the vat, and by heating the water, all the milk is heated together to 84 deg., when a sufficient quantity of the rennet, with just enough good, nice coloring is added, to turn the milk to a firm curd, and give it a shade as near the color of butter as possible.—I should have said, that in the cheese making season we do not make any butter; therefore the cream taken off in the morning, as mentioned above, is heated to 120 deg. Fahr., and turned back into milk at the time of putting in the rennet, and all stirred together. This is left to stand from thirty to forty minutes, or until all has thickened to a firm curd. One word

#### *About the Rennet.*

The Rennet should be well prepared, and great care should be taken to preserve it and keep it sweet. I am very certain that rennet changed, tainted, or in the least sour, is very injurious to cheese.

#### *Management of the Curd.*

When the milk has hardened, (as above described,) I take a curd knife composed of five blades, known as D. G. Young's curd knife, (which I am sorry to say is not in general use in this country,) using it as directed by him, which is, to hold the knife upright, drawing

it forward and back carefully, until the curd is cut into blocks of about one-half inch square. Start the fire slowly in the forenoon. Let it stand ten or fifteen minutes, then use the knife again very carefully, so as not to start off the cream, or as the common saying is not to start the white whey. Great care should be taken not to mash the curd, so as to make the whey come from the cheese, as this is the cream; therefore, the best of milk. It is thus carefully worked and carefully heated until all comes to 92 or 94 degrees of heat, when the fire is put out and the heating process stopped, and we call it scalded sufficiently for any cheese in any time of year, if cut as fine as it should be, and worked in a proper manner. I use the curd-knife until curd is as fine as desirable, which should not be larger than peas. The curd is then left to cool, still stirring it to hasten the cooling. When thoroughly cooled, the curd is put to press.

#### *The Press.*

A good press is indispensable to good cheese-making, and presses are like many other patents, very numerous. But, in my opinion, a press should be able to press at least two thousand pounds, especially for a large cheese. A cheese must be well pressed, and still not pressed so as to make it salvy, which is sometimes the case, and very much injures the cheese.

#### *How to Press.*

We always press a cheese two days. It is left in the press one day without being disturbed. When my next day's cheese is in the press, I then turn my cheese, made the day before, into a clean, sweet strainer, and it is pressed with nearly or quite double the pressure of the first day. When I desire a cheese of from eighty to one hundred pounds weight, I apply seven hundred and fifty or eight hundred pounds pressure the first day, and about fifteen or sixteen hundred the second day.

#### *Capping and Dressing.*

When the cheese is taken from the press, it is immediately dressed in a shirt of cotton—thin cotton called capping or sacking, made for this purpose. We cap them all over, especially our heavy cheese; they are then scalded over with boiling water to make the sack adhere closely to the cheese; we press lightly under the press for a few minutes, when it is taken to the dairy-room and left without greasing for eight or ten days, that it may dry, and the gas which it still contains may escape. There is then a coat of warm grease put on it to prevent its molding, (it should then be turned daily before greasing.) It should then be placed on a clean, dry shelf or table, and turned every day until well cured.

#### *Dairy-Room Ventilated.*

The dairy-room should be well ventilated,

airy, light dry room, in order to cure cheese as it should be. Notwithstanding, many of our dairy-men, and even in some sections of England, dairy-men say the room should be kept close and dark. This appears to me to be un-natural, as almost everything requires air and light in order to have beauty and perfection.

I have made cheese nearly for fifteen years, and have never found it a difficult matter to sell cheese made and cured as above, at the very highest market price. Sixty cows have been our number for three years past. It is not to boast, but it is said by cheese-buyers that I sold my cheese, last season, the highest of any man in this country.—*Silas N. Jones, North Bloomfield, Turnbull Co., O.*

### **Domestic.**

#### **Packing Eggs for Long Journeys.**

The only safe way of packing eggs is—1st.—Get a large hamper or box—put on the direction-card before packing—make holes for screwing the lid on; let there be no hammer used, but only screws and screw-driver. 2nd. Procure a box or hamper of such capacity that, when placed inside, you will have three or four inches space each way. Get some hay, which pull to pieces, separating to some extent, then a lot of old newspaper, cut up into lengths. To proceed (we suppose you have got the eggs) put each into the paper, twisting the ends of the paper sideways like a lady's curl wrapt up in an ordinary curling-paper, thus: egg, thin end downward; paper; place some hay in the box, then a layer of eggs in paper, then hay, and so on until the box is full; screw the lid on, put some hay in a box, then in another box, and all round, and at top, and fasten down. If screws, such as are used for stair-rods, were fastened into the four corners of the smaller box, and then a string tied from them to the four corners of the other box, all might be safer; also, if the large box, when filled, were swung in like way on board ship; but I do not think this is absolutely necessary, though advisable. The object of using the paper is, it keeps out all dust, and the ends acts as springs, as does also the hay. Bran and corn are bad, as there is much dust in both, and fresh air is kept away from the eggs; but the greatest fault is, they and the eggs pack into so solid a mass that there is not enough elasticity, and the consequence is the constant jars, so to speak, break the delicate membrane suspending the yoke in the shell, and the egg is "killed." Perhaps the following hint may be of use in the matter of packing eggs for long distances: the Dutch pack the plover's eggs for the English markets in strong wooden boxes with the husks of buckwheat, and we seldom have much breakage after the roughest passages.

and rough handling in transmission. They begin by covering the bottom of the box with a thick layer of husks, and so on till the box is nearly full, then fill in with husk, and pretty tightly putting on the lid. With the exception of an accident now and then, we don't have more than five in the hundred broken on the average throughout the season.

## The Poultry Yard.

### How to make Hens Profitable.

Mr. J. C. Thompson, of Staten Island, who takes an interest in all branches of husbandry, and pursues them with success, has contributed the following valuable observations on the keeping of poultry to the *American Agriculturist*. He has added since the publication in that periodical a postscript for the *Evening Post*.

"Most families in the country, and on the outskirts of cities, think they must keep one or more pigs to use up the offal of the family—or because it is the 'custom of the country.' Having tried pigs and become disgusted with the trouble, labour, expense, filth and noise—to say nothing of the inferiority of pork to eggs and poultry—I abandoned the former for the latter; the result has been quite satisfactory, and after several years trial, I feel confident the advantage is decidedly in favor of poultry. Here is my last years account: January 1, 1861, stock on hand, 70 fowls, of which fifteen died during the winter from unknown causes, leaving me 52 laying hens. From these I obtained in January, 409 eggs; in February, 439; in March, 681; in April, 959; in May, 835; in June, 801; in July, 719; in August, 603; in September, 421; in October, 332; in November, 286; and in December, 440. Total, from 52 hens, 6,925 eggs—equivalent, in bulk, to seven barrels, as a barrel packed for market contains just about 1,000 eggs.—About 8 eggs from the Leghorn or black Spanish breeds, weigh a pound. My 6,925 eggs therefore, weighed 865 pounds. Allowing the hens to weigh 5 pounds apiece, they each laid, on any average, three times their weight in eggs alone. As they hatched full a hundred chickens the weight of which, when ready for the table, must have been  $1\frac{1}{2}$  pounds each, the whole amount of food produced was over a thousand pounds, notwithstanding I killed off part of the old stock in June, July and August, depending on spring hatched chickens, which began to lay in August, to keep up a supply of eggs and replace those killed off. When we consider the amount of food (of the very best kind) produced in one year from so small a stock to start on, and then, too, the stock left whole at the end of the year, the advantage of poultry over pigs can be seen at a glance.

"To produce 1,000 pounds of pork will re-

quire a vast amount of labor, a vast quantity of food, and any quantity of noise—giving fresh food for only a short time and salt food for the balance of the year—and the stock not left whole to start on again, as in the case of poultry. The product in eggs was more than 6,925, perhaps over 7,000, as I detected a boy that had access to the hen-house for some time, in stealing them. The number named was actually collected. My stock is principally Leghorn; and it now costs \$3 per month to feed 75 head. As some may desire to know how the hens are managed, I send a brief description.

"THE HEN-HOUSE.—Mine is a lean to—10x16 feet—10 feet on the rear and 8 feet front, facing the south. A barn stands on the east and a shed on the west end, with a glass front, for a shelter and a feeding place in cold and wet weather. The roofs of both project three or four feet, which keeps the ground dry in front and about the entrance. The back and front of the house are lined or double boarded, and the front has three glazed sashes—furnished with inside shutters—a ventilator 16 inches square is placed in the roof with a valve hung at the bottom, to close more or less, as may be required, in cold and stormy weather.

"ROOSTS—A frame is made and hung to the rear of the house, which can be set at any desired inclination; the roosts are placed lengthwise on the frame, ladder-like, about 18 inches apart. As all fowls seek the highest roosts these are filled first, and others in succession. This brings them close together in cold weather. In warm weather the frame must be levelled to make them scatter on all the roosts and keep as cool as possible.—The floor being concreted, it is easy to clean, keeps out rats, and makes it dry. Under the roosts I place fine charcoal [a poor plan to use charcoal—Ed.] or dry earth, or muck to absorb the droppings; a few shovelfuls added each day keeps the house free from any bad odor. The rest of the floor should be covered with sawdust, dry earth, chaff or cut straw, for in cold weather, hens like to keep their feet dry and warm. Neither coal nor ashes should be put in the house, as they act on the manure and decompose the uric acid, thus wasting the ammonia, and making the house offensive.

"FOR NESTS—Use butter or lard tubs (which can be had at the grocer's for six cents each) set on shelves at the ends of the house, one or two feet from the floor—portable nests (with glass eggs) are best.—They should be often cleaned and supplied with fresh straw or hay. The grease on the tubs is a remedy against lice. Greasing the roosts at all the places where they touch the frame, and in fact, the inside of the house and roosts, with any kind of soft grease or fish oil is certain to destroy them, as they cannot live a moment in grease. A paint brush or

white-wash brush can be used for applying the grease, which should be done early in the spring, and again in summer, if it appears to be required.

**"MODE OF FEEDING.**—I give only sound grain; no other should be used. A variety is not objectionable. My standing dish is wheat screenings; this is always by them in a box slatted up at the sides for the purpose as a feeding box. In winter scalded corn meal or ground corn and oats is given to them cold in the morning; but the main food must be hard grains. They must be well supplied with finely cracked oyster shells, gravel and mortar, and green food in winter. Mine consume two or three heads of cabbage. They get bread scraps from the table, soup, meat, etc. In summer, grass, lettuce and cabbage are furnished daily in abundance—they will consume a great quantity.

**"YARD ROOM.**—The permanent yard is 50x50 opening into a grazing and rambling lot of 50x100, also used as a plum orchard. The fence is only 5 feet high, and by feeding well and clipping the feathers on one wing there is no trouble in keeping them at all times within the yard.

**"SETTING THE HENS**—To insure good healthy chicks, the hen should be set in March, and certainly not later than April. By having portable nests, when hens desire to set and become fixed in the habit in the setting season, they can be supplied with eggs (the date of setting marked on them in ink or pencil,) and any number of nests moved to a room for the purpose, which must be kept closed, and well supplied with food and water. The nests may all be set side by side, for if the hens should all leave their nests at once to feed, when they return they will each take a nest, although they may change places. This arrangement insures their setting steady, as they are not compelled to wander off for food, but return quickly to the nests and keep up the warmth of the eggs, and thus bring out strong chicks. By setting a number at one time, if some hatch half broods they can be put together with one hen. When a setting hen looks pale about the head it is evident she is lousy; clean and wash the nest, grease the hen under the wings, on the back and rump, wash the eggs in warm water, and return to the nest.

**"TREATMENT OF CHICKS.**—When first hatched they must be fed on bread soaked in milk; after three or four days, feed with cooked or scalded Indian meal three times a day; but finely cracked corn or wheat screenings, should be always within their reach; also clean water. The hens with chicks should be kept in coops for several days, the coops kept dry and clean and placed in sheltered places. With such treatment not five per cent. of chicks will be lost. In conclusion let me say, the secret of success is this. They must be young, well fed and cared for, and

small numbers—12 to 25—pay much better in proportion than large flocks.

J. C. THOMPSON,

"Tompkinsville, Staten Island, N. Y.

**"P.S.**—Since writing the above I find 75 hens will eat six quarts of Indian corn a day, they helping themselves to it, that is, a peck to one hundred hens. The test was made on Indian corn, that being the staple food for poultry."

## The Apiary.

### Bee Pastures.

Old and experienced beekeepers tell us that there is such a thing as overstocking a country with bees. That you can get too many bees for your pasture as easily as you can get too many cattle or sheep for your pasture. This, undoubtedly, is sometimes the case. It is, therefore, an object of some importance to enquire into the subject and endeavor to find out in what way bee pastures can be increased in any way. A little study into their habits and wants will put us on the right track.

We believe bees do not stop to enquire into the genus or species of the plant, shrub or tree on which they feed. They are not very particular whether it be on lowland or highland. They have been known to cross the water, five miles from hives on the main land to flowers that distance from them, on an island. Their only enquiry therefore seems to be the instinctive one, whether the flowers and fruits within their reach contain honey or not. The earliest bee pasture that we can furnish them in Maine, is maple sap. In warm days of our early spring, and before any flowers have put forth in our latitude, you will often see bees flitting about the sap troughs at the foot of maple trees in sunny situations, or on the surface of the stumps of maple trees that have been cut down during the winter, and from which the sap oozes out. It would not, therefore, be a bad plan to set small shallow vessels of maple sap in the vicinity of the apiary early in the spring, from which the bees might sip and separate the honey.

The next earliest source of food for them among us, is the willow. The several varieties of the willow blossom earliest, perhaps, of any thing, and from these blossoms the bees collect not only honey, but farina. It is, therefore, an object for bee keepers to not only preserve the willow, but to set them out in moist, waste places, if for no other purpose than for early bee pasture.

The red maple and the elm come next in blossom, and bees also visit them for the purpose of obtaining honey and other substances which they work up in their operations of the hive. By this time quite a number of shrubs and flowers have come into blossom, such as the

swamp pear, (*aronia*), the plum cherry, and subsequently the apple and pear. All of these become so many sources of food to the bees. Later yet, the basswood throws out a profusion of flowers, and the bees are always found abundantly around them when in blossom. It would be well to have more of these trees out by fences and road sides. They are highly ornamental as well as useful for bee pasture.

The locust, or yellow locust, is another tree which grows rapidly and blossoms profusely, of the flowers of which bees are very fond. These should be more extensively cultivated, though the borers sometimes make sad havoc with them.

Of all the flowers it is thought that of the white clover is most acceptable and most productive of honey to bees. This is a native of the country and will grow almost any where, especially if it be encouraged by sowing a little plaster on it.

Buckwheat is often sowed for no other purpose than to afford pasture to bees.

In addition to these, the other flowers of the fields and the gardens all add to the extent of the bee pasture, and should all be multiplied and cultivated wherever they can be conveniently.

The Russians sometimes cultivate quite extensively the common borage of the gardens for the use of bees, thinking, and probably not without reason, that it affords a good supply of honey, which is easily obtained by the bee. Perhaps some of our readers can think of other sources of feed to bees, the cultivation of which would enlarge the *area of honey* and make it worth the trouble to cultivate them.—*Maine Farmer*.

## Veterinary Department.

(Conducted by A. Smith, V. S.)

### Bots in Horses.

EDITORS CANADIAN AGRICULTURIST.—Under the above head of page 154 of the "Agriculturist" is a receipt, which it is said will generally afford relief in five or ten minutes. Feeling much interest in arriving at a right conclusion in this matter, I last year sent you an extract from Youatt & Skinner's work on the horse, wherein it was stated that bots, while they inhabit the stomach of the horse cannot give the animal any pain: that they cannot be removed by any medicine that can safely be administered, and that in due course of time they come away.

I have had some experience with horses for the past twenty-five years, and occasionally (for want of a better) have been obliged to be my own horse doctor; but I never yet saw a case of suffering from bots. I have heard of most extraordinary cases, such as the stomach being eaten through, and I was recently positively assured by an intelligent person that he had lost

a fine young horse from bots, where there was no symptom of the cause twenty-four hours before death, that he did not make a thorough examination after death, but that he found the wind-pipe full of bots.

I now address you under the hope that some of your readers who have had experience in such matters will state which is the correct treatment; to endeavour to expel them or to let them take their one course.

BRIAR.

### REMARKS.

The mucous membrane lining the stomach of the horse, is divided into two portions, a cuticular and villous. The cuticular is on the left side and is continuous with the cuticular lining of the oesophagus; this coat is covered by thick scaly epithelium and is thrown into folds, which folds disappear when the stomach becomes dilated. The mucous membrane of the right side is called the villous, and this portion, the true digestive stomach, the mucous membrane is thick, soft and pulpy.

Bots occur chiefly amongst young horses, grazing on damp coarse pastures, shaded with trees. The female fly deposits her eggs on the shoulders, legs, or other parts of the body within reach of the animal's tongue, by which they are carried into the mouth and thence to their common *nidus*, the cuticular portion of the stomach. It is the cuticular half of the stomach that bots inhabit generally, and from this circumstance, that they are fastened to a part not very sensitive, bots do not give rise to such pain and irritation as is frequently imagined.

The larva, or worm, being hatched and lodged in the stomach, immediately clings by means of its tenacula to the cuticular coat which it pierces, and so pertinaciously does the bot adhere, that it will frequently suffer its hook to be broken rather than quit its hold.

This larva is found very difficult to destroy and resists the action of most medicines, but there are certain times when they pass out, and then their removal can be expedited by certain medicines. An easy remedy is to rub down in hot water about three drachms each of aloes and assafoetida, and when the solution has got cool add to it an ounce each of turpentine and sulphuric ether; repeat the dose every second day for a week, leaving out the aloes if the bowels become too open. Along with such

treatment it is necessary to give good food and a change of diet.

When bots only exist in small numbers they are generally harmless, when a multitude they prove detrimental to digestion, by absorbing part of the juices necessary for that process.

Percivall in his work on diseases of the horse mentions that he recollects of hearing Professor Coleman say, that he knew of a case where bots appeared to have destroyed life, since after death the coats of the stomach appeared eroded in places, as well as the diaphragm, and some of them had made their way into the cavity of the chest.

### Inflammation in Animals.

▲ LECTURE BY PROFESSOR DICK, OF EDINBURGH.

(Concluded from Page 118.)

In the previous lecture we pointed out that in the web of a frog's foot, in which, from its transparency, the various processes which take place in it can be perceived with considerable facility by means of a microscope, the flow of blood through the minute vessels or capillaries becomes slower and slower, and at last comes to a complete stand-still, notwithstanding that the latter are dilated beyond their usual dimensions; and offer, therefore, apparently at least, less mechanical resistance to the onward passage of the blood than usual. We further pointed out that this remarkable stagnation of the blood in a part about to become inflamed is not due to any primary alteration of the blood corpuscles, in as much as these bodies exhibit no deviations from their usual properties in the vessels before they arrive at, and after they left, the part about to become the seat of inflammation, so that the cause of the remarkable tendency which the corpuscles show to adhere to each other and to the walls of the vessels, so as to cause stagnation of the circulation, must be looked for in some alteration which has taken place in the surrounding textures.

In order to understand the nature of the alteration which first takes place in the textures of a part about to become inflamed, so as to cause stagnation of the circulation, it will be necessary to notice the remarkable movements which take place in certain cells, called pigment cells, of the frog's foot, and which appear to have been first noticed by Brucke, of Vienna, in 1852, but more recently and more correctly by Mr. Lister in the Philosophical Transactions for 1858. It has been long known that the frog is capable of changing its colour under certain circumstances—becoming dark when placed in

a dark place, and assuming a brighter hue when placed in the light. This capability of the frog of changing its colour, although possessed to a certain extent by all the species of the frogs, appears to be best marked in the tree frog. Now, the lighter or darker hue of the frog at different times is due to changes in the pigment cells above mentioned. These cells are distributed, in great numbers in the substance of the true skin, and, in the web at least, are situated also on the walls of blood-vessels. On examining the web with the microscope, and directing attention to the pigment cells, they are seen to be black bodies consisting of a central portion, from which processes of various sizes radiate. On more careful examination each cell is found to consist, like all other cells of a delicate yet firm and elastic membrane, enclosing in its central portion a round colourless body, called the nucleus. The nucleus is usually situated in the centre of the cell, but sometimes it is found placed more to one side. In addition to the nucleus, the cell contains a transparent, colourless fluid, in which float an immense number of minute particles which, when viewed singly, have a brownish tint, but when seen aggregated in groups, present a coal-black appearance. The processes which proceed from the central cell likewise contain fluid and coloured particles, so that they are not solid outgrowths of the cell wall, but may be regarded, as in truth they are, tubular prolongations of the cell itself. These processes, where they arise from the central portion of the cell, are usually of considerable breadth, but as they pass outwards they soon ramify and split up into numerous slender, thread-like lines, which anastomose or become continuous with similar prolongation from neighbouring cells. All these processes, even the most minute, are hollow, and consist of a delicate membrane, continuous with that of the central cell, and are filled with a colourless fluid, in which coloured particles float. It follows, therefore, that the contents of the central cell can pass readily into the various processes which radiate from it, and *vice versa* the contents of the processes may, under other circumstances, pass into the cavity of the cell. Moreover, owing to the processes of one cell anastomosing freely with similar processes of neighbouring cells, the contents of one cell may mingle with those of other cells. It is doubtful, however, whether this actually does take place, but at all events we have here a remarkable series of tubes, along which the pigment particles and the fluids in which they are suspended may move, quite independently of the circulation. It is very probable, if not certain, that the contents of all cells undergo changes similar to those which will be described immediately, but owing to the absence of coloured particles and the consequent homogeneous appearance of their contents, the movements cannot be demonstrated. It is different, how-

ever, with the pigment cells. The dark pigment granules contrast strongly with the surrounding colourless fluid and cell membrane, so that any alteration of position which they may experience can be very easily observed.

We have already remarked that the frog is capable of changing from a dark, almost black, hue to a comparatively light appearance, and *vice versa*; and this is effected by a change of position of the pigment molecules in the cells. When the pigment granules are aggregated closely together in the cavity of the cell so as to form, under the microscope, a more or less rounded spot, the colour of the frog is light; when diffused through the cell, and in part through the tubular processes, the colour is darker; and when the pigments are still further scattered through the various ramifications of the cell, so that comparatively few remain in the central portion of the cell, the colour of the frog is almost black. Of course, there are some frogs which are never of a dark colour, but we always find that, without exception, the colour of the frog is darkest the more diffused the pigment granules are through the tubular processes of the cells, and lightest the more concentrated they are in the central portion of the cell. It was supposed by Brucke and Von Wittich that when the pigment was aggregated in the central portion of the cell this was effected by a shortening or contraction of the processes of the cell in which it was diffused, but this supposition was first shown to be erroneous by Lister (*Op. cit.*) On careful examination we find that the pigment moves from and towards the central portion of the cell quite independent of any change in the form and dimension of the cell and its processes. On the contrary, the pigment granules appear to be under the influence of a force or forces which reside in the central part of the cell, while at the same time they take place to a certain extent under the influence of the nervous system. If, for example, the frog be excited by laying hold of it so as to cause it to struggle, the pigment immediately becomes collected in the central part of the cell, and the animal turns pale. Again, if the animal is brought from a dark place, and exposed to a bright light, the same thing takes place; not as has been shown by the light stimulating the pigment cell directly, but by reflex action, through the medium of the optic nerve. In this case the stimulus of light is conveyed by the optic nerves to the nerve centres, and is thence reflected or sent to the nerves of the skin, and apparently exciting the pigment cells to action, cause concentration of the pigment in the central part of the cell. Concentration of the pigment in any given cell may, besides, be occasioned by gently irritating the part either mechanically or by chemical reagents. On the other hand, diffusion of the pigment into the processes of the cells appears to take place when the parts are in a state of quiescence, and seems to be caused by

the particles having a repellent action on each other, which comes into operation as soon as the attractive force which is seated in the centre of the central portion ceases to be exerted with intensity sufficient to keep the granules together.

Having thus endeavoured to describe as briefly as possible the nature of these pigmentary movements, let us next consider them when a part in which the cells are seated has been irritated to such a degree as to cause inflammation. We have already seen that one result of irritating a part to such an extent as to give rise to inflammation is to cause viscosity of the blood corpuscles, and in this way to hinder the circulation, notwithstanding that the calibre of the vessels is greater than usual. If now we irritate strongly a small portion of the web of the frog's foot by placing a drop of turpentine or a little mustard on it, we shall find a remarkable difference in the behaviour of those pigment cells which are seated directly under the irritant from those which are situated at a little distance. Let us suppose that at the commencement of the experiment the web is dark and the pigment consequently diffused throughout the processes of the cells, we shall find that while the pigment still remains in a state of diffusion in those cells which are placed nearest the irritant, it becomes concentrated in those cells which are further removed from the irritant, and on which the irritant acts with comparative mildness. On continuing to watch the web, it is found that no movements take place in these cells which are situated at the point of the irritation. The pigment granules remain in the same state as they were at the moment of the application of the irritant, while the surrounding cells which were more gently stimulated exhibit movements of their molecules as usual.

It may now be asked what is the cause of the stoppage of the molecular movements in those cells seated at the point of irritation. We have seen that the molecular movements are in all probability caused by a force which resides in the centre of the cell. We are, therefore, forced to the conclusion that the movements in question are destroyed by the irritant acting so strongly as to paralyse the central force. If the irritation, however, has not been too great nor too long applied, the central force recovers its power, and the pigment again exhibits its usual movements; at the same time, the part begins to swell from the formation of the fibrine and the effusion of serum, and the various signs and symptoms of inflammation ensue. Bearing in mind that what takes place in the pigment cells likewise takes place in all the other cells of the part, we come to the conclusion that the *first stage of inflammation consists in paralysis of the functions of the part*, and it is owing to this that the blood corpuscles, which flow through the part, become viscid, and stop the circulation; in the same way as they become viscid, and adhere to each other when removed from the ves-

sels and placed beyond the influence of the vital action of the textures. When the irritation has been so great as to cause *permanent* paralysis of the functions of the part, then mortification or death ensues. When the irritation has been more gentle, the part resumes after a time its functions, but in a disordered manner so as to give rise to the various phenomena of inflammation. The degree of these subsequent disorders is determined partly by the nature of the part, and partly by the amount of irritation and consequent paralysis of the functions of the part which has taken place. When the irritation has been slight, the reactionary phenomena will, *ceteris paribus*, be correspondingly mild; while if the irritation has been severe, suppuration, ulceration, &c., will take place, and the structure of the part will be destroyed to a greater or less extent.

### Scab.

We are apt to congratulate ourselves that scab, with many other evils, has disappeared before the improved practice of modern agriculture. But although usually comparatively circumscribed in all its attacks in this country, it is apt from time to time to spread, and occasion much trouble, expense and loss. Extensive graziers inform us that many of the English hill sheep are this spring infected, and that much care will be required to prevent the evil extending with the distribution of the stock which generally takes place during the next three months. Even as far south as the Cotswolds the plague appears, and large graziers and dealers assure us that they will take no sheep home without a full and explicit warranty of soundness.

Scab, as is now well ascertained, is nearly allied to mange in dogs and itch in man, and depends upon the presence of minute creatures—a species of *acarus* or mite—which burrow in the skin, causing the familiar distressing itching, the inveterate rubbing, and the irritable pimples skin, which, as the disease proceeds, becomes scurfy, bare, and scabbed. The unfortunate Highlandman of immortal fame, irritated by the “Scottish Fiddle,” as it is technically styled in the north, blessed the Duke of Argyle for his considerate erection of rubbing posts, and the sheep afflicted with scab make an equally liberal use of all objects against which they can rub, and in this manner the *acari* are frequently deposited, and transferred to the next visitor. The *acari* are of two sexes; the females, however, are the most active and troublesome, burrow at once in the skin, leaving as the mark of their entrance only a minute red speck, like the point of a pin. In eight or ten days a little swelling appears, which gradually softens and becomes pustular, and by the fifteenth or sixteenth day breaks, and allows the escape of the female, who appears with her brood of from eight to fifteen

young ones clinging round her legs. These are soon distributed, bury themselves in the skin, and if unchecked multiply with great rapidity. Warm weather is especially favorable to their propagation, and hence the spring weather generally aggravates and increases the complaint, and even causes its re-appearance in those cases which seemed during the colder months to be perfectly cured. Troublesome and provoking in every case, scab is especially so amongst ewes and lambs; for not only do the dressings disturb and annoy the ewe, but the offspring are frequently weakly, thrive badly, and soon show unmistakable evidence of the disease.

Shepherds often understand tolerably well the treatment of scab, and various dressings are in good repute. A mixture of tobacco water, oil of tar, and soft soap is very effectual, and, like any other applications, must be well rubbed in. It does not answer now to adopt the old prescription of allowing the “salve to sink to the sair;” it must be applied with smart and diligent friction. Four ounces of tobacco infused in hot water, a pint of oil of tar, a pound of tar, a pound of soft soap, will, with the addition of water, make a gallon of dressing, or quantity sufficient for three score of ordinary sized sheep. A mixture of mercurial and iodine ointments, or an alternate dressing of each, is also a good application, but must be used with caution, especially in damp weather, as the mercury is apt to become absorbed, and cause slow poisoning. During the past month a gentleman in this neighborhood lost five ewes, which died apparently from the unduly liberal use of mercurial ointment applied for the cure of scab. Unlike the rest of the flock, these five had been subjected to a second dressing, and the shepherd, naturally anxious to get rid of the pest, was probably too liberal with his remedy. The weather, moreover, was afterwards wet, which might possibly facilitate the absorption of the poison and aggravate its injurious effects upon the system. The animals gradually became unthrifty and weak, lost flesh, and dwindled for five or six weeks, when four died, and one, being so hopelessly ill, was killed. We are told that the only notable appearances were wasting and paleness of the flesh, “soft rottenness” of the liver, and in the uterus a dead, swollen, partially putrid lamb. Cases of this description, and they are by no means uncommon, ought to render farmers more careful than they are in the use of remedies so potent as mercurial ointment. The articles mentioned by no means exhaust the list of agents employed in scab. The old-fashioned sulphur ointments or liniments are still in use, but not very trustworthy; solution of chloride of lime, or bleaching powder, is also recommended, but is less effectual than solutions of arsenic, corrosive sublimate, chloride of zinc, or the other remedies already advised. In addition to the medical treatment, entire separation of

the sound from the tainted stock, must of course, be strictly enjoined, and as the acari, deposited about the bark of trees, or on other such objects, will in mild weather retain their vitality for some days, no sound sheep should, for at least a fortnight, have access to the fields from which the scabbed stock have been removed.—*North British Agriculturist.*

## Miscellaneous.

### The Horse-Hair.

In Professor Agassiz's interesting paper on "Methods of Study in Natural History," the second of the series in the *Atlantic Monthly*, we find this anecdote of an animal known to almost all country boys :

A gentleman from Detroit had the kindness to send me one of those long, thread-like worms (*Gordius*) found often in brooks, and called horse-hair by the common people. When I first received it, it was coiled up in a close roll at the bottom of the bottle, filled with fresh water, that contained it, and looked more like a little tangle of black sewing silk than anything else. Wishing to unwind it, that I might examine its entire length, I placed it in a large china basin filled with water, and proceeded very gently to disentangle its coils, when I perceived that the animal had twisted itself around a bundle of its eggs, holding them fast in a close embrace. In the process of unwinding, the eggs dropped away and floated to a little distance. Having finally stretched it out to its full length, perhaps half a yard, I sat watching to see if this singular being that looked like a long, black thread in water, would give any signs of life. Almost immediately it moved towards the bundle of eggs, and, having reached it, began to sew itself through and through the little white mass, passing one end of its body through it, and then returning to make another stitch, as it were, till the eggs were at last entangled again in an intricate net-work of coils. It seemed to me almost impossible that this care of offspring could be the result of any instinct of affection in a creature of so low an organization, and I again separated it from the eggs, and placed them at a greater distance, when the same action was repeated.

On trying the experiment a third time, the bundle of eggs had become lessened, and a few of them dropped off singly into the water. The efforts which the animal then made to recover the missing ones, winding itself round and round them, but failing to bring them into the fold with the rest, because they were too small, and evaded all efforts to secure them, when once parted from the first little compact mass, convinced me that there was a definite purpose in its attempt, and that even a being so low in the scale of animal existence has some dim consci-

ousness of a relation to its offspring. I afterwards unwound also the mass of eggs, which, when coiled up as I first saw it, made a roll of white substance about the size of a coffee-bean, and found that it consisted of a string of eggs, measuring more than twelve feet in length, the eggs being held together by some gelatinous substance that cemented them and prevented them from falling apart. Cutting this string across, and placing a small section under the microscope, I counted on one surface of such a cut from seventy to seventy-five eggs; and estimating the entire number of eggs according to the number contained on such a surface, I found that there were not less than eight millions of eggs in the whole string.

**MANAGEMENT OF DOGS.**—Dogs kept constantly in the house must be let out four or five times a day for a few minutes, otherwise it is cruel to punish them for want of cleanliness. All dogs, whether long or short haired, are better for being brushed once a day; it conduces to the health, and greatly increases the comfort of the animal. A dog who is well brushed regularly, seldom requires washing, and is never infested with vermin; but if the dog is to be washed let it be done with yokes of eggs and not with soap, which irritates the skin, inflames the eyes, and by temporarily depriving the skin of its natural oily secretion, makes the dog extremely liable to be chilled afterwards. The washing with the yoke of eggs may be managed as follows:—Let the dog stand in an empty tub, rub the yolks of two, four, or more eggs by degrees into his coat, adding lukewarm water a little, until the dog is covered with a thick lather. When it is well rubbed in over the whole coat, pour clean warm water over the dog till the egg is entirely washed out. The advantages of this process are, that the dog's coat does not lose its glossy appearance afterwards, and that the whole operation can be performed quickly and quietly, and without any splashing of water or rough handling. To remove fleas, take enough soft soap to rub into the whole coat of the dog; add to this a teaspoonful more or less, according to the size of the dog, of spirits of turpentine; rub this mixture well into the roots of the hair, adding a little warm water to make it reach the skin. Let this remain on for a quarter of an hour, then plunge the dog into a warm bath, and rub off the mixture with the hand. Care should be taken not to let it get into the eyes, and to wash it completely out of the skin.—*House Dogs and Sporting Dogs; by J. Meyrick.*

**GOSSIP ABOUT COACHES.**—The Egyptians used a car or box, upon wheels, and the word "coach" is supposed to be of Hungarian origin. In 1294 the citizen wives of Paris rode in them. The oldest (used by ladies) were called whirlicotes, or open cars. The mother of Richard II. rode in one; and in 1474 the Emperor Frederick III.

went to Frankfort in one. Stow says William Boone, a Dutchman, in the sixteenth century introduced coaches into England; while Strutt, in his *Manners and Customs of the English*, says that Walter Ripon in 1555, made for the Earl of Rutland the first coach in England. The Duke of Buckingham, in 1619, was the first to have a coach drawn by six horses, but he was eclipsed by the Duke of Northumberland, who drove eight in ridicule. State coaches gilt are mentioned in 1609. Charles I., had one, and specimens can now be seen in the Lord Mayor's "Gingerbread," and her Majesty's gilded one-Stage coaches gilt are mentioned 1664, and Sorbriere (1664-70) says he went in one from Dover to London, "drawn by six horses one before another," but this is what we should now term a waggon. Fosbroke gives a list of thirty different kinds of coaches, and our friend Taylor in 1623 writes that he heard of "a gentlewoman who sent her man from Charing-cross to Smithfield to hire a coach to carry her to Whitehall; another did the like from Ludgate-hill to be carried to see a play at the Blackfriars." In 1634 one Capt. Bailey established the first hackney coach stand in London. He set four coaches with men in livery by the Strand May Pole, and this example being soon followed by others, a writer of the time adds that "sometimes there are twenty of them together, which disperse up and down," and he frequently adds, that "everybody is much pleased with it."—(Garrard) In 1636, there were more than 6,000 hackney-coaches in London, a proof of the public's appreciation; but in 1660, Charles II. issued a proclamation forbidding their stopping in the streets, for that they must be hired from the stables, &c. The *Weekly Register*, December 8, 1773, tells us that "these hackney gentlemen who drive about the city and suburbs of London, have by their overgrown insolence obliged the Government to take notice of them." The *Gentleman's Magazine* records, that on September 23, 1751, a man ran a coach wheel from the Old Bailey to the eleven mile-stone at Burnet and back in three hours fifty-one minutes, for £50. He had four hours to do it in. By statute 3rd Geo. I. c. 7, sec. 2, 800 hackney coaches were licensed at 5s. each weekly.—*City Press*.

**POTATO BLIGHT.**—M. Lemaire advocates coal tar as a preservative against the potato blight. He incorporates two parts of coal tar with 100 parts of dry and loose earth, and strews this mixture over the ground to be planted with potatoes, after which the field is ploughed or dug in the usual way. In this manner the coal tar is buried to the depth of 20 centimeters or thereabouts, and the potatoes planted in it thrive perfectly, and are never attacked with the blight. Mr. Lemaire has also made the discovery that potatoes planted in a part of the same field, which had been purposely left without coal tar, contracted the disease at the same time that the others were free.—*Galignana*.

**A LIVING FROG FOUND IN COAL.**—The following is an extract from a letter received on Wednesday last in this city, by John Russell, Esq., from the manager of his Try Nicholis Colliery, Com Tytery, near Newport:—"Our men in the heading in the rock vein coal yesterday, March 10, in the fall of coal in the face of the heading, found in a hole in the pricking, in the top of the coal and in the nine-inch bed of coal, a live frog. The hole was not more than 3½ inches in diameter and this found in a soft holding. There is a slight hollow over the coal where it was found. It began moving about as soon as it was released, but seems larger and more lively to-day. It is kept shut up in clay to exclude the air from it. Now this is 200 yards below the surface, where this little thing was found, and I do not suppose any one can form an idea how long it must have been there. I intended having it kept for you until you returned"—(Signed) L. W. Rees. [Mr. Russell is going to send to the Great Exhibition a block of coal, between ten and eleven feet long, selecting the piece in which the frog was found, the *locus in quo* being exactly in the centre and the block will be so cut out that the frog and its strange domicile will be clearly shown in front]—*Worcestershire Chronicle*.

**SUNSET AMONG THE ICEBERGS.**—The book is open to record. The sun on the rugged hills of Labrador, a golden dome; Bell Isle, a rocky blue mass, with a wavy outline, rising from the purple main pricked with icebergs, some a pure white, others flaming in the resplendent sunset like red-hot metal. We are sailing quietly as an eagle on the still air. Our English friends are heard singing while they walk the deck, and look off upon the lonesome land where their home is waiting for them. All that we anticipated of the sunset, or after-sunset, is now present. The ocean, with its waves of Tyrian dye laced with silver, the tinted bergs, the dark blue inland hills and brown headlands underlie a sky of unutterable beauty. The west is all one paradise of colours. Surely, Nature, if she follows as a mourner on the footsteps of the fall, also returns jubilant and glorious to the scenes of Eden. Here, between the white light of day and the dark of the true evening, shade and brightness, like Jacob and the angel, now meet and wrestle for the mastery. Close down among the gloomy purple of the rugged earth, beam the brightest lemon hues, soon deepening into the richest orange, with scattered tints of new straw, freshly-blown lilacs, young peas, pearl and blue intermingled. Above are the royal draperies of the twilight skies. Clouds in silken threads and skeins; broad velvet belts and ample folds black as night, but pierced, and steeped, and edged with flaming gold, scarlet and crimson, crimson deep as blood, crimson fleeces; plumes tinged with pink, and tipped with fire, white fire. And all this glory lies sleeping on the shore, only on,

the near shore of the great ethereal ocean, in the depths of which are melted and poured out ruby sapphire, and emerald, pearl and gold, with the living moist blue of human eyes. The painter gazes with speechless, loving wonder; and I whisper to myself, "This is the pathway home to an immortality of bliss and beauty." Of all the days of the year, this may be the birthday of the King-of-day, and this effulgence an imperial progress through the grand gate of the west. How the soul follows on in quiet joy, dreaming of lovely ones waiting at home, and lovely ones departed, waiting with Christ! Here comes that wondrous lines of Goethe, marching into the memory with glowing pomp: "The setting sun! he bands and sinks—the day is over-lived. Yonder he hurries off, and quickens other life. Oh! that I have no wing to lift me from the ground, to struggle after, for ever after him! I should see in everlasting evening beams, the stilly world at my feet, every height on fire, every vale in repose, the silver brook flowing into golden streams. The rugged mountain, with all its dark defiles, would not then break my godlike course. Already the sea, with its heated bays, opens on my enraptured sight. Yet the god seems at last to sink away. But a new impulse wakes. I hurry on to drink his everlasting light—the day before me and the night behind—the heavens above, and under me the waves. A glorious dream! as it is passing he is gone." Here come the last touches of the living colouring, tinging the purple waves around the vessel. Under the icebergs hang their pale and spectral images, piercing the depths with their mimic spires, and giving them a lustrous, aerial appearance. The wind is lulling, and we rise and fall gracefully on the rolling plain. "The day is fading into the later twilight, and the twilight into the solemn darkness." No, not into darkness; for in these months, the faint flame flickering all night above the white ashes of day from the west circling around to the north and east, the moonlight and the starlight and the northern light; all conspire to make the night, if not more beloved than day," at least very lovely. A gloomy duskiness drapes the capes, beneath the solitary cliffs of which lies half entombed a scattered iceberg, a ghostly wreck, around whose dead, white ruins the mad surf springs up and flings abroad its ghastly arms. Softly comes its sad moaning, and blends with the plaintive melodies of the ocean. Hark! a sullen roar booms across the dusky sea—nature's burial service and the funeral guns. A tower of the old iceberg of the cape has tumbled into the billows. We gather presently into the cabin for prayer, and so the first scene closes on the coast of Labrador. —*Rev. Lewis Nobles' Iceland.*

**PREVENTION OF SEA-SICKNESS.**—Let a person on shipboard, when the vessel is bounding over the waves, seat himself, and take hold of a tumbler nearly filled with water or other liquid, and

at the same time make an effort to prevent the liquid from running over by keeping the mouth of the glass horizontal, or nearly so. When doing this, from the motion of the vessel, his hand and arm will seem to be drawn into different positions, as if the glass were attracted by a powerful magnet. Continuing his efforts to keep the mouth of the glass horizontal, let him allow his hand, arm, and body to go through the various movements—as those observed in sawing planing, pumping, throwing a quoit, &c.—which they will be impelled, without fatigue, almost irresistibly to perform; and he will find that this has the effect of preventing the giddiness and nausea that the rolling and tossing of the vessel have a tendency to produce in inexperienced voyagers.—*Albionæum*

**THE JAY'S VOLUBILITY.**—One of the most remarkable peculiarities of the jay is the volubility of their sounds. The alarm note the bird utters on the appearance of danger, or even of a stranger in its haunts, is extremely harsh; but it has a love note peculiarly soft, "yet so low and apparently cautious, that it seems whispering to its mate, as if to hide their affections and labours from the other tenants of the grove. Even then it is very imitative, and though it does not attempt the songs of the warblers, it is very adroit at bleating, screaming, neighing, and in short, imitating all the harsher sounds." Bewick says: "We have heard one imitate the sound made by the action of a saw so exactly, that though it was on a Sunday, we could be persuaded that the person who kept it had not a carpenter at work in the house. Another, at the approach of cattle, had learned to hound a cur dog upon them, by whistling and calling upon him by name. At last, during a severe frost, the dog was excited to bite a cow big with calf, when the poor animal fell on the ice, and was much hurt. The jay was complained as a nuisance, and its owner was obliged to destroy it." Mudie, another careful observer, remarks: "Words in which the letter r occurs soonest learned, not only by the jay, but by most birds that can be taught to articulate." That is easily accounted for by the unyielding nature of the mandible which forces the air to come out between the upper part of the tongue and the palate, on which that trills. A man cannot easily pronounce the r in any but Northumberland fashion, if he grins the while; and those who use the tongue simpering and softly merely touch, but do not pronounce it.—*Cassell's Popular Natural History.*

**ORIGINAL ANECDOTE OF BURNS.**—As Lord Crawford and Lord Boyd were one day walking over the lands in Ayrshire, they saw Burns ploughing in a field hard by. Lord Crawford said to Lord Boyd, "Do you see that rough-looking fellow across there with the plough? I will bet you a wager you cannot say anything to him

that he will not make a rhyme of." "Done said the other; and immediately going up to the hedge, Lord Boyd cried out, "*Baugh!*" Burns stopped at once, leant against the plough, and, surveying his assailant from head to foot, he quietly answered—

"It's not Lord Crawford, but Lord Boyd,  
Of grace and manners he is void—  
Just like a bull among the rye,  
Cries "*Baugh!*" at folks as he goes by."  
The wager was of course won.

### Editorial Notices, &c.

#### Provincial Exhibition at Toronto, 22nd to 26th September, 1862.

In our last issue we were unable to announce decisively the exact days on which the Provincial Exhibition would take place this year, in consequence of it having been discovered that the days which had been chosen by the Board were the same as those selected by the New York State Society for their show at Rochester this year. As it was, of course, desirable to avoid a collision of dates if possible, some correspondence, as stated in our last, took place with a view to a satisfactory arrangement.

As it appears from the correspondence that the New York Society had published their list, and made various arrangements which would render it exceedingly difficult to change their days, the Upper Canada Board of Agriculture, after full consideration of the subject, decided that our Show should take place one week earlier than first intended, viz., during the week, commencing on Monday, September 22nd. The Exhibition will accordingly be held at Toronto, this year, on the days above stated: 22nd, 23rd, 24th, 25th and 26th September. It would be seen in our last that the rules or regulations, connected with the Exhibition have been remodelled and amended, and some new prizes offered. We shall have some remarks to offer on these points on another occasion.

#### BOARD OF AGRICULTURE.

THE Office of the Board of Agriculture has been removed to 188 King Street West, a few doors from the late location adjoining the Government House. Agriculturists and any others who may be so disposed are invited to call and examine the Library, &c., when convenient.  
HUGH C. THOMSON,  
Toronto, 1861. Secretary.

#### FOR SALE.

A LOT of thorough bred improved Berkshire Pigs of various ages.

R. L. DENISON,

Dover Court.

Toronto, Aug., 1861.

#### Notice of Partnership.

THE Undersigned have entered into Partnership as Seedsmen and dealers in all kinds of Agricultural and Horticultural Implements, under the firm of James Fleming & Co.

JAMES FLEMING,

GEORGE W. BUCKLAND.

#### NOTICE.

JAMES FLEMING & CO., Seedsmen to the Agricultural Association of Upper Canada will carry on the above business, wholesale and Retail, at 126 Yonge-st., 4 doors North of Adelaide-street, until next July, when they will remove to the new Agricultural Hall, at the corner of Queen and Yonge-streets.

JAMES FLEMING will continue the business of Retail Seedsmen and Florist at his old stand, 350 Yonge-street.

Toronto, January 1st, 1861.

#### THOROUGH BRED STOCK FOR SALE.

THE SUBSCRIBER has for Sale Durham and Galloway Cattle, male and female. Leicester, Cotswold, and Lincolnshire Sheep, male and female.

January 1, 1862.

JOHN SNELL,

tf.

Edmonton, P. O., C. W.

#### IMPROVED BERKSHIRE PIGS

FOR SALE by Mr. Denison, Dover Court, Toronto.

Toronto, April, 1862.

#### A Thorough Bred 2 Year Old

#### AYRSHIRE BULL

FOR SALE, by Mr. Denison, Dover Court, Toronto.

April, 1862.

## GEORGE LESLIE, NURSERYMAN.

**OFFERS FOR SALE, THIS SPRING, A GENERAL assortment of Nursery Stock, consisting of**

|                              |     |  |
|------------------------------|-----|--|
| Apples, Standard and Dwarfs, |     |  |
| Cherries, do.                | do. |  |
| Pears, do.                   | do. |  |
| Plums, do.                   | do. |  |
| Peaches, do.                 | do. |  |
| Appricots and Nectarines,    |     |  |

## GRAPE VINES,

NATIVE AND FOREIGN.

**CURRENTS, GOOSEBERRIES, RASPBERRIES, BLACKBERRIES, STRAWBERRIES, &c., &c.**

The stock of Agricultural Seeds is large and well selected. The vitality of each sort is carefully tested, and their genuineness may be fully relied upon. A large stock of Peas, Timothy, and Clover:

Spring Tares,  
" Wheat,  
Black and White Oats.  
Swede Turnips, Purple top.  
" " Green top.  
" " Laing's Improved.  
" " Skirving's Improved.  
White Globe Turnip.  
Yellow Aberdeen "  
" Altringham "  
Waite's Eclipse Turnip.  
Stubble or Six Weeks "  
Mangel, Long Red.  
" Long Yellow.  
" Yellow Globe.  
" Red Globe.  
" New Olive Shaped.  
Sugar Beet.  
Field Peas, several varieties.  
Marrowfats, " "  
Barley, two and four rowed.  
Buckwheat.  
Indian Corn, several varieties  
Alsike and White Clover.  
American Orchard Grass,  
Kentucky Blue Grass.  
English Rye Grass.  
French Lucern.  
Cow and Rib Grass.  
Carrot, White Belgian.  
" Long Orange.  
" Altringham.  
Parsnip, Hollow Crowned.  
&c., &c., &c.

Also a full and general assortment of all kinds of Garden Seeds: a Catalogue of which, with directions for sowing, can be had on application. Agricultural Societies ordering Seeds, will be supplied on liberal terms. Country Merchants supplied with complete assortments of Garden Seeds on Commission, neatly put up in boxes of 200 papers each, for retailing at five cents a paper. Also a large assortment of Flower Seeds, embracing the novelties of the season.

No. 126 Yonge Street, Toronto.

March, 1862.

4t.

## VETERINARY SURGEON.

ANDREW SMITH, Licentiate of the Edinburgh Veterinary College, and by appointment, Veterinary Surgeon to the Board of Agriculture of Upper Canada, respectfully announces that he has obtained those stables and part of the premises heretofore occupied by John Worthington, Esq., situated corner of Bay and Temperance streets, and which are being fitted up as a *Veterinary Infirmary*.

Medicines for Horses and Cattle always on hand. Horses examined as to soundness, &c.

Veterinary Establishment, Corner of Bay and Temperance Sts.

Toronto, January 22nd, 1862.

## The Imported Thorough-Bred Horse "Charon,"

WILL stand for Mares, at Mr. St. George's Farm, Second Concession, and travel as follows, from 1st May: He will leave his own stable on Monday at noon, proceeding down Yonge Street and stopping as required. Will remain at Steele's Tavern all night, will go on to Toronto on Tuesday morning, and stop till Wednesday at noon at Bond's Livery Stables. Will proceed to Weston, and stop there all night; return home on Friday, by Yonge Street; will remain all night at Steele's Tavern, and arrive at his own stable on Saturday morning.

CHARON is by "Archy," by "Camel," by "Whalebone," by "Waxy," by "Pot-8-o's," by "Eclipse," &c, &c. His dam, "Styx," was by "Defence," out of "Proserpine, &c. See Studd Book. Any one acquainted with the English Turf and Stud Book will see that there is not in America a better bred horse than Charon. His pedigree includes the most celebrated sires, and the most fashionable blood of England. Charon was in training for the Derby when he was purchased and brought to Canada. See Ruff's Guide.

TERMS: Season Mares, \$12; Single Leap, \$8; Thorough bred, \$20, and \$12, single leap; Groom's fee, 50 cents.

Mares will be taken into pasture, and carefully attended to on Moderate Terms.

Address H. Q. St. George, Esq, Oakridges Post Office.

Oakridges, April 17, 1862.

## FOR SALE.

A LOT of thorough bred ESSEX Pigs,—bred from recently imported 1st prize animals and have this season taken premiums at both Township, County, and Provincial Exhibitions.

JAMES COWAN.

Clochmor, Galt P. O., Oct. 19, 1861.

THE  
Canadian Agriculturist,

OR

JOURNAL AND TRANSACTIONS OF THE BOARD OF AGRICULTURE  
OF UPPER CANADA

VOL. XIV.

TORONTO, JUNE 1, 1862.

No. 11.

The Provincial Exhibition.

As announced in our last issue the holding of the Exhibition of the Agricultural Association of Upper Canada will take place in Toronto, September 23rd—26th—and preparations are now making to render the accommodation to all classes of exhibitors as ample and complete as possible. Hitherto there have been some grounds for complaint among farmers that the arrangements for the accommodation of cattle and other kinds of live-stock, have not been fully equal to the requirements of the case; a defect which it is believed will be remedied for the future, as extensive permanent buildings have now been erected in four of our principal cities; an expense that will not have to be incurred again, and leaving therefore each locality to make better and more extensive rangements for meeting the wants of the farmer, whose interests though not exclusive are confessedly the most important of any in these displays of the skill and industry of the country. Two new erections of a permanent character for the accommodation of horses and cattle are in the course of erection on the show grounds in Toronto and another in the proximity of the original exhibition building for the reception of the implements and putting machinery into motion. Pens for sheep, pigs, and poultry will be more convenient and ample than heretofore. And although it is confidently believed that the

amount of material in every department of our Provincial industry will be considerably larger this year than on any former occasion, the local committee in Toronto have commenced preparations on what is considered will prove a proportionate scale. In estimating the amount of accommodation required at these national competitions, there is a tendency as the exhibition grows in years to *improve in quality*, which after all is the main test of the character and utility of these great gatherings. It is in no point of view desirable that any thing be sent to a Provincial competition which is devoid of positive excellence; what might be considered as passable at a township or even a county show should be well considered before sending it to occupy valuable space in a Provincial display, which would be mainly made-up of what is really superior. We make these observations not with a view to discourage intending exhibitors, but rather to stimulate all such as have any thing really worth seeing to send it forward, that the *status* of our Provincial shows, the quality and excellencies of their material, may be progressively improved and elevated.

We would particularly call the attention of intending exhibitors and others interested in the exhibition to the rules and regulations appended to the prize list, as published in our last; copies of which are being printed in pamphlet form, to be circulated among agri-

cultural and mechanics' societies throughout the province. It will be seen that the departments of live stock and agricultural productions are to be this year thrown open to general competition, so that we may reasonably expect a number of competitors appearing from the adjacent British Provinces and the neighboring States.

### The Weather and the Crops.

Up to the date of this issue of our Journal the weather has been very favourable for getting in the spring crops, which work, with the exception of Swede Turnips, and some other fallow crops, may now be said to be completed. For Swede Turnips the first and second week in June, or say about the 10th of this month, has generally been found to be the best time of sowing, provided the weather and the state of the ground be suitable. For the growing crops this season there has been a great lack of moisture. In this portion of Canada, there can scarcely be said to have been more than one day's good rain since spring work commenced. Fall wheat generally looks pretty well, and did not suffer much from winter killing or late frosts, but spring wheat and other spring grains are seriously retarded for want of rain, and unless we soon have sufficiently copious showers the meadows will give but a short crop. An esteemed correspondent from West Northumberland writes us:—

"Our crops have been mostly all got in in good order, and, notwithstanding the spring was late, vegetation is as far advanced now as it usually is at this season of the year. The weather was favourable for getting in the crops well. Rain is wanted now, and unless we have some soon our hay crop will be light, indeed all crops want rain."

The accounts are pretty much the same from all parts of the country, west, as well as east, but we hope that a few days of plentiful rain may soon put a different face on the appearance of the fields. The Kingston Whig of a late date says:—

"Rain is badly needed, at least most farmers are crying out for it. Peas and potatoes are doing very well. In this section of Canada, the crops have been put in exceedingly well, and in ample time, the weather being very favourable for spring work. But the country wants rain badly, and the hay will suffer if rain does not

soon fall in abundance. As little winter wheat is sown in this neighbourhood, we can offer no opinion as to its state of forwardness, but have heard no complaints as yet. A large breadth of rye has been planted, and that looks well.

### Reply to the Address of Condolence to Her Majesty.

The following correspondence was inadvertently omitted in a previous issue of our journal. It is in acknowledgement of the Address of Condolence to Her Majesty, on the occasion of the death of the late Prince Consort, adopted at the convention of the Agricultural Association held in this city on 30th January last.

QUEBEC, 19th April, 1862.

Sir,

I am directed by the Governor General to transmit to you the enclosed copy of a despatch from the Secretary of State for the Colonies, conveying Her Majesty's gracious reply to the address of condolence from the Agricultural Association of Upper Canada.

I have the honour to be,  
&c., &c., &c.,

DENIS WILLEY,  
Governor's Secretary.

H. C. THOMSON, Esq.,  
&c. &c., &c.,  
Toronto.

[Copy No. 89.]

DOWNING STREET,  
4th April, 1862.

My Lord,

I have the honor to acknowledge the receipt of your Lordship's despatch No. 48, of the 14th ultimo, together with an address of condolence to the Queen from the Agricultural Association of Upper Canada.

I have to request that you will inform the Agricultural body from whom the address emanated that it has been laid before the Queen; and that Her Majesty was much impressed by the expression of sympathy and devotion.

I have, &c.,  
(Signed,) NEWCASTLE.

VICOUNT MONCK,  
Governor, &c., &c. &c.

### International Exhibition.

33 CLAPHAM RISE, S.,  
LONDON, ENGLAND,  
6th May, 1862.

Editor of the Canadian Agriculturist.

Sir,—Having arrived at Liverpool early on the morning of Saturday the 3rd instant, after a very pleasant voyage across the ocean, we

took the train at 9 a.m., and arrived at the Easton Station at 2 p.m., took a cab to our comfortable quarters as above, and on Monday 6th, I paid my first visit to the Exhibition. I found our Canadian Department presenting a very creditable appearance, and, from the extensive and well arranged specimens of mineralogy and woods, attracting much attention. The articles of the exhibition are not nearly all in their places yet, and the arrangement of the departments is not completed, but from the cursory observations I was able to make,—and I found every one who had an opportunity of making the comparison of the same opinion, it will as an exhibition far exceed that of 1851. I was particularly struck with the improvements in the Implement Department, to which I, as a matter of course, gave my first attention. There a great many new inventions of a very useful kind, and old inventions perfected and improved. Steam is brought largely into use in performing the most important operations. I only at present make general observations; when I have made a more particular examination, I may be able to give some details that will interest your readers. The English, Irish and Scotch manufacturers seem all to have exerted themselves most successfully in getting up a show of useful labor saving implements, which exceeds by ten times anything of the kind I have ever seen. Our neighbors, the Americans, notwithstanding all their difficulties, will make a very creditable appearance. Though they have not nearly so much on exhibition as in 1851, they have not more than one-fifth of the space they had on that occasion, and will in consequence make a better appearance. Their department is not yet complete in its arrangements. The French are also behind in their arrangements, but will have a splendid display. The articles on exhibition from Sheffield, Birmingham, Huddersfield, and indeed from all other parts of England, Scotland and Ireland are beyond description. The value is immense. One firm alone has more than a million pounds worth of articles on exhibition.

Australia makes a good show, particularly in her cereals. The grain is very superior.

I think I may safely say that the International Exhibition of 1862 will be an entire success. The building itself externally has not so elegant an appearance as its predecessor, but much taste and artistic skill have been displayed in its interior, and the effect will be very imposing and grand.

With respect to the appearance of this beautiful country at this season, it is most delightful. The trees in full foliage and bloom, the early sown grain covering the garden-like cultivated fields, the luxuriant grass, all produce a most pleasing effect. No finer season of the year could be selected for a visit to England than the month of May. The country is truly lovely, and must be seen to be appreciated.

We were unfortunate in not getting here in time for the opening of the exhibition. Owing to the delay on the railroad we were two days behind time in leaving Portland. The opening was a most splendid affair, as you will see by the English papers.

May 7th.

I yesterday again went to the Exhibition, and examined the Nova Scotia and New Brunswick departments. They are very good, many articles of superior quality. Vancouver's Island sends some of the finest grains I ever saw. The colonies generally are well represented. We went in the afternoon to Sydenham Palace, and were really enchanted with it. There is nothing can be imagined more delightful than the surrounding scenery. We have to go again to make an examination of those departments of the palace that we could not get through yesterday. The drive from where we are, about four and a half miles, is very fine; the fields are looking so beautifully green and luxuriant that it produces the most pleasing sensation to see them. There have been several showers within the past few days and the air is warm. Vegetation is rapid; the tares are fit to cut for food for animals, and you see loads of them carried about. The month of May has been, so far, all that could be desired, and the people seem to enjoy it.

This is rather an important day at the Exhibition, as the juries are to meet, some six hundred, and organize for the commencement of the general examination, which will probably occupy the whole of this month. Professor John Wilson is the party who has the general management of this matter. That gentleman occupies the same position on this occasion that he did in 1851. The organization is to commence to-day at 11 o'clock, and as I must now close in order that this may be in time for the mail, I will say no more at present.

Yours, &c.,

E. W. THOMSON.

#### SECOND LETTER.

London, May 12th, 1862.

Since I wrote last, there have been quantities of rain falling almost every day; and it has been somewhat cold, though not unusually so for the season, people say. The weather ten days since, I find now, was considered unusually warm. Notwithstanding that last week has been cold and wet, the trees and fields maintain their cheerful and delightful appearance. The exhibition attracts its thousands, and all who do not hold three guinea season tickets pay their five shillings entrance fee.

There is still a good deal to be done to get everything in its place; but there is enough in complete order to employ visitors for weeks in examining and admiring. The French de-

partment is one of the most attractive. The manner in which their Agricultural products are displayed is highly creditable to them, and exceedingly interesting. Australia is displaying most splendid samples of wheat, wool, and fancy woods. There is in that department a very novel article in the way of a machine for reaping, or rather gathering the wheat, and delivering it perfectly clean in a box, from which it may be bagged or deposited on a grain cloth. The straw, chaff and dust are left in the field and burned. The machine is not cumbersome; and, I am told by Australians, is found to be most efficient. It certainly is a valuable labor-saving machine, but would not answer where it is an object to save the straw. But in that country they do not require the straw, and therefore find it the best way to burn it, the ashes adding something to the fertility of the soil. The whole collection from Australia is very fine; and it is not to be wondered at that it attracts the attention of parties desirous of emigrating. The French department is still incomplete; but it is already very attractive, and will be much more so. The Austrian department is still behind, but will be good. Norway has a very fine display, particularly in woollen manufactured goods, in which it is amongst the best. Turkey will be well and creditably represented. I have no doubt it will be three weeks yet before all is arranged. There are still goods to arrive; and, although the time for receiving them has expired, they are receiving them notwithstanding, and every day unpacking and fitting up.

May 13th.

The Jurors are at work, but their progress is slow; and it will take a long time to get through all the classes. I am in Class 3, Sec. A, Agricultural Produce. The most of the Jurors are foreigners; but as they are able to make themselves understood in English, we get on very well. They are intelligent, and thoroughly understand what they are about. We were to-day in Tasmania and New Zealand; both of which colonies exhibit fine specimens of agricultural produce. The specimens of Indian Corn from New Zealand are very good, and in all the varieties I have seen of that grain, from the very small white to the largest horse-tooth variety. But I think the variety known with us as 12 Rowed Yellow is the best amongst them.

There is a good deal of novelty in the stuffed skins of animals and birds from all those southern colonies. The animals are also very attractive. Ornamental woods are also very well represented; but for the useful woods, for general and commercial purposes, it is generally admitted that Canada excels all other countries. Our collection in that department is exceedingly good. The wools

from the Australian Colonies attracted much attention, and deservedly so, for they are very fine. There are also many samples of cotton from the Southern Colonies, of various degrees of goodness; but I am not qualified to judge of their merits. We shall, doubtless, have the recorded opinion of the jurors by and by, as well as the result of their decisions upon all the fibrous substances, which are very numerous and from various countries; and amongst these Jamaica and some of the other West India Islands hold conspicuous places. Russia, Norway, Sweden, and some of the other portions of Europe will excel in fibrous productions.

A person visiting this grand display of the productive resources of the various countries of the earth, though returning daily, is impressed each day with wonder and admiration at the wonderful displays of the Divine goodness of the Great Ruler of the Universe who has so amply provided for the wants and for the gratification of the desires of the whole human race.

Your's, &c.,

E. W. THOMSON.

### On the Cultivation of Flax.

We have of late devoted considerable space in his journal to the culture and preparation of Flax, and as the subject is exciting more earnest and general attention than heretofore we lay before our readers the following remarks from the *Irish Farmer's Gazette* of May 3rd, which were drawn up by Mr. Thos. Berry, formerly steward to Lord Gormanstown, at the request of several parties in the County of Wilts, who were desirous of carrying on its cultivation. Mr. Berry grew last year in that part of England 182 acres of flax, a sample of which gained the first prize of £15, at the Royal Agricultural Society's Show at Leeds. Steam cultivation was employed in the preparation of the land, and the results were in every way most satisfactory. The following remarks embrace the details of the cultivation of Mr. Berry's prize crop, and will afford our readers some useful suggestions:

Being solicited by parties feeling desirous of growing flax (as an extra and remunerative crop) to state to them my method of preparing the soil, sowing the seed, and after management in preparing it for delivery to the flax mill, I most willingly comply with their request.

In the first place, the soil must be stirred 8 or 9 inches deep either with the plough or some sort of cultivator or grubber; many varieties of which last mentioned implements are now in use amongst agriculturists generally, and most of

them, I find, by going through the soil twice or thrice, will effectually move it to the requisite depth. I have found Bentall's cultivators to answer well for that purpose; and in preparing the land for flax, I much prefer them to ploughing it. Double the quantity of work can be done in one day with the same number of horses with the cultivators, than with ploughs, the soil is much more pulverised, and all weeds are brought to the surface. The plough turns the weeds under, if any, in the surface of the soil, which must afterwards be found, and only with considerable labour got out.

This deep tillage I should advise being done in the autumn, or as early in the spring as circumstances will admit of, being governed by the state of the soil; for the land generally becomes dry towards the middle of March, and from that period to the middle of May. The sowing of the flaxseed may, therefore, take place in the month of April, that being the month in which flax sowing is most extensively carried on throughout the United Kingdom.

If the soil got its first tilling in the autumn, or long previous to the time of sowing, the cultivators, or grubbers, as they are termed, large and fine harrows must be freely used, and rollers also as well, if the clods are *hard*, in order to *bring the surface to as fine a tilth as possible*; in fact, the tilth cannot be *too fine*. If the surface after the several harrowings be still rough and hard, the rollers used cannot be too heavy. When the soil is very dry, two or three horse rollers will be found to be required, and if used most frequently after the harrowing, will produce the very best results, in speedily pulverizing the soil sufficiently fine for the reception of the seed. The surface should always be rolled the last thing previous to the seed being sown with seed troughs or seed barrows (so called in some parts of this country), at the rate of two bushels per acre, statute measure. Two men, with a couple of these machines, will sow from 20 to 30 acres daily. I should insist on their going over *all* the ground, one of them wheeling his machine, say from north to south, the other from east to west—each man being provided with marking poles to guide the width and to which he should wheel quite straight to each, sowing after the rate of one bushel per acre with each machine. The reason of this cross sowing is for the purpose of having the seed distributed quite regular on the rolled surface of the soil; as a most important point is, by this process to obtain an even and good quality, as well as a full average crop of fine flax. When the two men have completed the *first* square of a few acres, the other men and boys will commence harrowing and rolling, to finish with, first harrowing in the seed with the finest seed harrows that can be procured, and if fine seed harrows cannot be had, chain harrows in most cases will answer the purpose quite as well. The seed does not require

being covered more than one inch beneath the surface by the seed harrows. I would suggest rather *less* than *more*, as the surface must be well rolled afterwards, if the land be *dry*, such being the last process of sowing. If the land be very dry, the heavier the roller the better; the dry or moist state of the soil must be the guide for the rolling, whether light or heavy rollers be used throughout the whole process of working the land during the sowing.

Flax is sometimes drilled an inch deep and six inches wide, at the rate of from  $1\frac{1}{2}$  bushels to 2 bushels per acre: this method affords an opportunity of hoeing the weeds with very small and narrow hoes; not more than 2 inches wide. When the ground is perfectly dry this last operation should be performed. When the flax crop is under a foot in height a good number of hands should be put at the work (that is, when the weather and soil permit of the hoers and weeders executing their work), as all the flax sown otherwise than by the drill must be weeded by the hands, and not with hoes. I scarcely need to mention that all the weeds that are accumulated on the surface of the ground under preparation for the reception of the flax seed should be gathered up and taken off; the implements found most useful for that purpose are chain-harrows, horse-rakes, hand-couch rakes and 3 and 4 prong forks—the latter for putting it into the carts. I have described the preceding operations as being performed by *manual* and *horse* labour; but the preparation of the soil for the sowing of the seed can be more fully carried out by steam cultivation.

I prepared, in the year 1861, more than 100 acres by the use of steam, and upwards of 82 acres by horse and manual power, for the flax crops produced at Horton, Wilts. The crop there was very superior, indeed, both as to quantity and quality, and for a specimen of which a first prize of £15 was awarded to T. L. Henly, Esq., of Calne, Wilts, at the R. A. S. show at Leeds in that year. The crop is fit to pull in the month of July, or early in August, which takes place when the seed balls are found to turn from a *green* to a *pale brown* colour, and the stalk turned *yellow* two-thirds up its whole length. The cost of pulling flax is from 10s to 20s. per acre; but the cleaner the crops are from weeds, so much less will the charge of pulling it be than the latter sum named.

The flax, when sufficiently ripe, as before described, is pulled by holding the tops of the flax in one hand, the other being placed about half-way down the handful of flax straw; it is pulled with a jerk, and if any dirt adheres to the roots of the flax a blow or two against the leg of the person pulling, in most cases, will cause it to drop off, a very desirable thing, as dirt amongst the flax and seed is very injurious. The handful of flax that is pulled is laid on a band of 9 or 10 flax straws—handful succeeding handful until a sufficient quantity is on the band; then when

tied the same as wheat makes a small sheaf of about 18 or 20 inches in circumference. The sheaves are stooked the same as wheat sheaves, of from 10 to 12 in a stook, but there are some who prefer stooking only 6 sheaves in a stook; in both cases the stooks should be turned if one side is more ready than the other to carry and rick, that each side of it may have an equal share of the sun to dry the fibre. The object of putting only 6 sheaves in the stook is, because of the convenience of pitching them in one forkful on the cart or waggon when carried, and therefore prevents loss of seed, and it is also found to dry sooner than when a much larger quantity is put together in stooks. The flax, when only a *small* quantity is grown, is put in small *round* ricks. When a *large* quantity is grown, the flax is put in *square long* ricks, 10 feet wide at bottom, 8 or 10 feet high in the side, and then a short roof thatched as soon as finished. Or if not *immediately* thatched, it must be well covered to prevent wet getting to the flax. If such, however, should by neglect take place, then very considerable injury will most probably be found to be done to the flax in question. This system of carrying the flax without steeping it is for the warm water system of preparing flax at the manufactory, and when the grower disposes of his crop to the flax manufacturer, for which class these remarks are written.

After the crop of flax is carried, it will prove an excellent plan to skim the surface of the ground about 3 inches in depth with the common skim plough, Bentall's cultivator, or, in fact, any implement that will be found to perform the work in an efficient manner. Then harrow and cart off (or burn on the ground) all refuse flax and weeds that can be gathered up upon the surface. After all this is performed the ground can either be ploughed or worked by cultivators of steam or horse power. The land may then be sown with rape, late turnips, rye, or vetches, or planted with cabbages adapted for sheep feeding in the months of April and May; of these the thousand-headed cabbage ranks as one of the very first. The seed of this cabbage should be sown either in March or April, for planting out in the months of August or September. If the land be manured after the flax crop, the same as clover stubbles or lea are for wheat, as good a crop of wheat can be grown *after flax* as ever can be grown *after clover*. In proof of such being the fact, it will only be necessary for me to refer any party to see the present beautiful growing crop of wheat *after flax* on Townsend Farm, Horton, in the parish of Bishop's Cannings, near Devizes, in the county of Wilts.

The flax crop can be grown to yield an average crop on suitable soils almost after any other crop has preceded it. The soils best suited for its growth would be found to be strong loams and clay soils; the clays on chalk and limestone formation would prove as good as any chalk, or

limestone brash will be found to grow excellent crops of flax. Green sandy soil, I have no hesitation in stating, will also grow good flax crops. If the land be well prepared for the reception of flax seed, and the soil also suitable for that purpose, *it will be found that has more to do towards producing an average crop of flax than anything else has; a vast deal more so than manuring for it with bad tillage.* Lands heretofore were very rarely, indeed, manured for growing flax, although latterly I have known it in some cases to be done.

A good crop of flax can be grown after two white straw crops, (say, wheat and oats), producing three or four ton per acre on suitable soil. well tilled for the putting in of the flax seed. The flax always seems to me to answer well in following oats after grass and clover leas; and the best results, I am certain, have been proved to follow this course when adopted, in most instances, on many farms.

In the northern counties of Ireland, where more flax is found to be grown than in any other parts of the United Kingdom, the growers there make it a general practice, when their land is cleaned, to sow clover seed amongst their flax, and the growers' most sanguine expectations have always been realized by the system thus adopted. Crops of clover produced in this way are always found to be far better than those produced by any other method, which can be easily seen and proved by any observer who may be travelling through these districts. The same convincing proofs of the entire success of producing superior crops of clover in England have been witnessed, I know, in various parts thereof. I will here mention, by way of illustration, one instance only of the *fondness* which I know clover has of growing amongst the flax crop. J. Parry, Esq., of Allington, near Devizes, Wilts, sowed a field of flax in the year 1860. The crop proved to be a very superior one. In the following year, 1861, he mowed a crop of clover off the same field, without previously sowing any clover on that field. It was red clover, too, which makes it the more remarkable, it is found to be almost always more rare for *red* clover to come indigenous than *white*. When clover seed is grown with the flax crop, I would suggest that the land should be previously made perfectly clean, and freed from all couch in particular, and then it might be sown in the same quantity per acre as if sown with any other crop, and it should be observed that the clover seed is sown at the same time of sowing the flax seed, before the roller goes over the ground the last time, *i.e.*, after the flax seed has been harrowed in. The clover seed may also be sown after the flax crop has sprung up not exceeding six inches in height. When the clover seed is sown amongst the growing flax crop, it must be left on the surface, for the purpose of moist weather forcing its growth.

I have known that as good crops of clover as ever grew have been produced in this manner when sown with barley or oats. If the flax crop is drilled, the clover seed may be sown either before or after being hoed; if sown after the hoeing of the flax crop, the surface will generally be found to be sufficiently loose for the reception of the clover seed, which must be allowed to remain for the rain to strike it into the soil, which will then be found speedily to promote its growth.

Grass seeds may be sown at the same time as the clover seeds amongst the flax, or at a later period if preferred. Grass seeds are as advantageously sown when the flax crop is taken off the land in August as *previously* thereto, and in this case it gives the clover a better chance of keeping stock, as I have always found that the young grass does not, in *after* sowing, grow predominant over the clover, to destroy it. The clover grows and flourishes well after the flax is pulled.

Carrots are sometimes grown with the flax crop, and fair average crops, to my knowledge, have been produced by sowing from 3 lbs. to 4 lbs. of carrot seed broadcast per acre. In this case the carrot seed should be sown at the same time the flax seed is sown, previously to the last harrowing with the fine seed harrow and the *last* rolling. From 2 lbs. to 3 lbs. per acre may be drilled at two feet distance; and if the flax seed is drilled, the carrots must be drilled across the flax drills.

The variety of *red* carrot called the "Intermediate," is the best for sowing with the flax crop. This variety of carrot is well known by its dwarf top, which falls down on its hollow crown, which resembles the hollow-crowned parsnip. This carrot is found to be one of our very best for the vegetable markets, and is one of, if not the most nutritious for all kinds of farm live stock. If the carrot seed is sown where the flax seed is drilled, it should be sown fresh before the hoeing; and in both instances the seed should be soaked for 48 hours in water or liquid manure, 10 or 12 days previously to its being sown, which is done to cause its early growth, and to come up at the same time as the flax seed—an important point. When taken out of the water, or the water strained from it, the seed should then be mixed with sand or ashes, or both sand and ashes mixed together, and afterwards well rubbed with the hands. Its proportions are two pecks of sand and ashes to 1 lb. weight of carrot seed. This is the quantity generally used to cause the seed to separate, but more may be added if found to be requisite for the sowing or drilling of the carrot seed.

Drilling the carrot seed across flax drills is very convenient for thinning out the carrots to their proper distances, from 7 to 10 inches in the row.

Much prejudice once existed against the growing of flax in this country; but this will be now

seen to be an antiquated prejudice, handed down to us by our forefathers, who then knew but very little, or next akin to nothing, of the useful art of making manure, and still less of preparing artificial manures. They were in the habit of sowing the flax after they had exhausted the land to the very utmost by sowing cereal (or, more plainly speaking, white straw) crops, at that time not at all considering that they had exhausted their land, previously to the flax crop being sown thereon, and yet, strange to say, expected the land to yield a good crop of wheat after the flax crop; and when that desired object could not possibly be obtained, the flax crop was considered to be the sole cause of their disappointment.

If land has become exhausted by cropping, and *wheat* being the desideratum of the grower, after his flax crop has been secured and got in, he has then only to manure his land with farmyard manure, or with such artificials that are found to be the most suitable dressing for the wheat crop.

It must, I am sure, be obvious to any observant person that the *roots* of the *flax* are *not* so constructed as to exhaust any soil, the small (I may say), very fine tap roots only from 2½ to 3 inches long, with its beautiful thread-like fibres, about one inch long growing around it, has been satisfactorily proved by scientific men as not to exhaust the soil anything equal to our corn crops. The flax fibre is principally formed by atmospheric power.

Finally, *the advantages of growing flax* are:—The grower of flax gains a crop that is in many instances more profit to him than his *best wheat crop*; and that after his land will not yield to him a remunerative crop of any kind without the aid of manure (either from his fold-yard, or artificial). The clear profit of the flax crop will, I am persuaded, after selling it in the straw, enable him to purchase artificial manure for six times the quantity of land which his crop of flax grew upon, which is, let me say, a very considerable item of economy in farm expenditure, as well as combining many other advantages in the succeeding crop, as before explained; as also affording him the earliest opportunity of autumn tillage, if he choose to follow that after the flax crop be carried in August, or, perhaps, July, according as the season may be.

#### Dr. Letheby on Diseased Meat.

[We take the following extracts from Dr. Letheby's report, respecting the sale of diseased meat in London. The Doctor is the medical officer of health, and has been very energetic in the discharge of his important duties.—These are matters requiring to be looked after in the more populous towns of this continent.]

"In the course of the last fortnight the (dis-

cers have seized 4,763 lbs. meat, and 111 head of poultry and wild fowl, as unfit for human food. It consisted of 59 sheep, 3 calves, 14 pigs, 27 quarters of beef, and 45 joints of meat; 3,269 lb. of meat were diseased, 182 lb putrid, and 1,312 lb. were from animals that had died from natural causes. Some of this meat was little better than carrion, and having been condemned by the justice, he submitted that the the city solicitor should be instructed to take further proceedings. The practice of sending diseased meat to the city markets is again on the increase, and it was to be regretted that in a few cases the salesmen do not give the assistance to the officers which they ought. On Saturday last one of the inspectors seized the carcass of a sheep which had been slaughtered while in a state of acute disease, and had been sold as human food by Messrs. Bonser & Sons, of Newgate market. Those gentleman complained in a public manner of the act of the inspector, and stated that although the animal was diseased, and the meat not of first quality, it was, nevertheless, fit for human food. The terms and directions of the act of parliament are so precise, and the responsibility of the inspector's duty so serious, that he has no alternative but to seize such meat. By the 26th clause of the City of London Sewers Act, 1851, it is declared that if, after the seizure of such meat by an inspector, and upon further examination by him (the medical officer) it is found and declared to be diseased, or unsound, or unwholesome, or not fit for the food of man, 'the same shall be burned or destroyed, or otherwise disposed of in such a way as to prevent the same from being exposed for sale, or being used for the food of man. In the present case, the meat was not only diseased, but the animal had been killed while in a state of high fever from acute inflammation of the lungs and pleura, and was manifestly unfit for human food. This conclusion was derived, not merely from the fact that there were pleural adhesions between the lungs and chest, for these alone are of small importance, and are never regarded as serious signs when they are of old standing. It is rare, indeed, to find an animal entirely free from them, although its flesh may be in the soundest condition. They are, in fact, the signs of disease which have passed away. In the present case, however, the whole of the walls of the chest were covered with recently effused lymph, which was hanging upon them in pulpy threads. The pleura was in a state of active inflammation, and the animal, at the time of its death, was suffering from acute pleura-pneumonia.—The whole system, therefore, must have participated in the disease, and have been affected with concomitant fever. The meat of such an animal, however good it may appear, cannot be good for human food, and the inspector would be wanting in his duty if he had failed to seize

it. It may be that the disease had lasted but a short time, and that the act of a butcher had anticipated the wasting effects of the malady and the final process of nature; but none of these circumstances can render the flesh wholesome, or make it other than the act of parliament designates—'diseased and unsound.'—Unfortunately, it is a common practice with farmers and cow-keepers at the present time to slaughter animals afflicted with a hopeless disease, in order that their carcass may be saved for the shambles. There is hardly a cow-house in the metropolis which is not continually furnishing diseased animals to the butchers. Very recently these houses have been inspected by Mr. Gamgee, the principal of the Veterinary College in Edinburgh, and he has stated publicly, in the last number of the *Edinburgh Veterinary Review*, and elsewhere, that the diseased cows of the London cow-houses are invariably sent to the city slaughter-houses to be killed for food.—One cow-keeper of the city told him that, in July last, out of an average stock of 30 cows, he sent upwards of a score to the butchers.—Considering how prevalent disease has been for the last two or three years among the cows of London, it is very probable that thousands of animals have in this way been disposed of. The practice is not without danger; for although it may generally pass unnoticed, it now and then shows itself in an unmistakable manner. In the month of November, 1860, the effects were witnessed by the medical officer on rather a large scale. A quantity of cow beef was bought at Newgate Market by a sausage maker at Kingsland, and made up into sausages in the usual way. The meat was not of first quality; for the sausage-maker observed such meat never is, but is always quite second rate. It was part of a cow that had been sent to the butcher from the London cow-house. Epizootic diseases were prevalent at that time in the cow-houses of London, and it is very probable that the animal was affected with one of them. It was a lean cow, and had ceased to give milk. This was all the dealer would confess; but the flesh of the animal told a terrible story. Of 66 persons who partook of the sausages made from it, 64 were attacked with the symptoms of poisoning, and the severity of the symptoms were in direct proportions to the quantity eaten. In several cases where members of the family had not partaken of them, they alone escaped, and people far away from Kingsland, who had bought the sausages of a second dealer suffered likewise. The effects were those of an animal poison, they were sickness, purging, giddiness, great prostration of the vital powers, intense irritation of the bowels, and in one case death. The matter was referred to the medical officer by the coroner for investigation, and it was also fully inquired into by Dr. Tripe, the medical officer of health for the District where the accident occurred. Both were

of opinion that the effects were clearly due to the sausages ; and as the most careful chemical and microscopic examinations did not discover a trace of mineral or vegetable poison, the conclusion was that the meat of the sausages was unsound. With such a fact, and many others of a like description, before him, he should be wanting in his duty if he permitted the sale of diseased meat. He added that it was not an uncommon practice for butchers to dress for the market the bodies of animals that had not been slaughtered, but have died from accident or disease. This practice, he said, is equally reprehensible. About a month ago the matter was contested with Messrs Bonser & Sons, of Newgate Market, who sold the carcase of a dead sheep, as it is termed, for food. As in the present case, they insisted that the meat was sound and wholesome, although for aught he knew the sheep might have been accidentally poisoned with arsenical sheep-wash.

"The rules which he had laid down for the guidance of the inspectors in the matter are, that they are to seize the meat of all animals which have not been slaughtered by the butcher, but have died from accident or disease.— That they are to seize the meat of all animals killed while in a state of acute disease, or which have wasted from lingering illness ; and, lastly, that they are to seize it when unsound from putrefaction or disease.

"They were the wholesome rules that had been acted on from very early times, and are most religiously observed in the present day by the Hebrews, who have brought them down from the remotest antiquity. They are the rules of almost every continental state, and were strictly followed by the ædiles of ancient Rome. Finally, they are indicated, as well as sanctioned, by the laws of this city, and have been more or less observed in every town in all times. It can hardly, therefore, be said that the exercise of the authority of the commissioners of sewers in this matter is an innovation, or that the rights and privileges of the butchers' trade are unnecessarily interfered with ; and even if they were, it is proper to remember that the preservation of public health is above all such considerations,"

### Rearing Calves on Milk and Linseed Meal.

The following remarks on a very important department of farming, from a recent number of the *Irish Farmer's Gazette*, will be found to contain much that is suggestive and useful :

When a calf is first dropped it is covered with a thick slime which Dame Nature teaches the cow by instinct to cleanse by licking it off, and if she shows any disinclination, the country people, to induce her to do so, sprinkle it with a little salt and fine oatmeal. This is necessary for the calf's comfort, cleanliness and health, and is

thought by many usefully medicinal to the cow and on every account should be encouraged. If the calf is permitted to suck the cow it will be more difficult to make it take its meals from the pail, and also fret and annoy the cow, which will not give its milk freely but retain it for its offspring. But though it will be necessary to prevent the calf sucking its dam for these reasons, it should be fed on the cow's first milk or beestings, which nature designs as its most nutritious food ; and it is also medicinal, cleansing the bowels of the pent up meconium or fecal matter secreted there during its confinement in the womb. It should, therefore, get a sufficient portion of this naturally medicinal aliment four times a day, say a pint and a half at time, so as not to keep it fasting too long, and, at the same time, not to overload the stomach. The calf should get a portion of its own dam's milk as long as it retains its peculiar medicinal quality, which may be known by its coagulating upon being heated or boiled ; but older calves should not get any of it, as to them it would be hurtful.

After the calf is a week old a little skim milk may be gradually mixed with the new milk, and after a fortnight, a little fine oatmeal, bean, pea, or linseed meal mucilage may be added gradually, which will enable the industrious and economical housewife to save her milk for the production of butter or cheese, and rear her calves also.

No doubt but that the best and most proper food for the calf is its own dam's milk : for it is a true food, in which the components of nutrition are so nicely balanced by the all-wise and beneficent Creator as to set at nought all human compositions ; but it is of so much value for human consumption that it becomes necessary to economize it and make imitations of it, though at a very humble distance ; and thus it is that science comes to our aid. Professor Johnson says in his "Lectures on Agricultural Chemistry," "that while the calf is young, during the first two or three weeks, its bones and muscles chiefly grow. It requires the materials of these therefore, more than fat, and hence half the milk it gets at first may be skimmed, and a little bean meal may be mixed with it to add more of the *casein* or curd, out of which the muscles are formed. The costive effects of the bean meal are to be guarded against by occasional medicine if required. In the next stage more fat is necessary, and in the third week at latest, full milk should be given, and more milk than the mother supplies if the calf requires it ; or, instead of the cream, a less costly kind of fat may be used. Oil-cake finely crushed, or linseed meal, or even linseed oil, may supply at a cheap rate the fat which, in the form of cream, sells for money ; and instead of additional milk, bean meal in large quantities may be tried, and if cautiously and

skillfully used, the best effects on the size of the calf and the firmness of the meat may be anticipated."

This Scientific note from Professor Johnson has engaged the attention of many stock masters in Ireland, and amongst the rest, Mr. C. Beamish, of Cork, who adopted and brought it to a regular system on an extensive scale. His formula for compounding the mucilage is as follows:—Thirty quarts of boiling water are poured on three quarts of linseed meal and four quarts of bean meal. It is then covered up close; and in 24 hours added to 31 quarts of boiling water then on the fire, pouring it in slowly, and stirring it constantly to prevent lumps, with a perforated wooden paddle, so as to produce perfect incorporation. After boiling 30 minutes, the prepared mucilage or gruel is put by for use, and should be given blood or luke warm to the calves, mixing it in small quantities at first with the milk, say one fourth mucilage with three-fourths milk, progressively increasing it, so that by the end of a fortnight it will be in equal parts; by the end of the third week, one and a half mucilage to one part milk; by the end of the fourth week the mucilage may be given in double the quantity of milk, and skim milk substituted for new milk, and by the end of the sixth week, the mucilage may be gradually increased in the proportion of two and a half to one of milk, and from that out till the tenth week the milk may be gradually reduced, so that by that time they may be fed wholly on mucilage till they are fifteen or sixteen weeks old, when they may be weaned.

During all this time, if too early in the season to put out the calves, they should be comfortably housed, well ventilated, and kept perfectly sweet and clean, a little sweet hay tied in bundles, and suspended so that they may play with it, and learn to nibble and eat it, and a little pounded chalk, mixed with salt, given in troughs to lick at pleasure, which prevents acidity in the stomach, and the undue formation of cud; small lumps of linseed cake should also be given in troughs, which they will soon learn to suck, if a little pains are taken to put a bit in their mouths after they have taken their meals of milk and mucilage. When housed it will be advisable to have a separate pen for each calf of sufficient size to walk about, so that they don't get into the habit of sucking each other, and swallowing the hair, which, uniting with the curd, by the regurgitating process going on in the stomach, forms round balls, which are indigestible, and is the fertile cause of the death of many promising animals. The following scale of quantity of milk or milk and mucilage combined for each calf may be useful, but should be altered according to circumstances:—For the first week the calf may get from 3 to 4 quarts daily; from the second week, 4 to 5 quarts; the third and fourth weeks, 5 to

7 quarts; fifth and sixth weeks, 8 to 10 quarts; sixth to eight weeks, 10 to 12 quarts per day, and so on, increasing the quantity about 1 quart per week per calf till weaning time.

Some parties do not give so much liquid food per day, but make it up by giving them finely cut roots, dry oatmeal, &c., but the animals are much too young for such food, though they may get the minced roots, so as to train them into their use. Hay tea is an admirable thing also to mix with the mucilage and milk, as it contains a large amount of nutriment in a soluble form.

In the summer time the calves may be left out on the grass, both day and night, in a fortnight after they are calved, and fed as already described they should be in the house; but a warm, sheltered paddock should be provided for them, and in wet weather they should have access to a covered shed.

### Straw as Food.

By C. W. JOHNSON, F. R. S.

(Concluded from page 297.)

In one portion of this essay the Professor closely and elaborately examines the nutritive and non-nutritive portions of the various kinds of straw met with in the stack-yard. Of the non-nitrogenised or carbonaceous substances found in straw, he observes: "Their use in the animal economy is of a two-fold character—either to supply the materials for the formation of animal fat, or to support respiration, and consequently animal heat. These different carbonaceous substances are not, however, equally well adapted to either of these uses, and may be divided, according to the fitness and readiness with which they fulfil the one or the other functions, into—

1. Fat-producing substances.
2. Heat-producing or respiratory substances.
8. Indigestible substances.

"To the first belong the oil, fat, and waxy matter, which in straw, as already mentioned, seldom amount to much more than 1 per cent. Oily and fatty vegetable substances are eminently well adapted to the laying on of fat in animals, inasmuch as the composition of vegetable fat is analogous if not identical with the several kinds of fat in the bodies of animals. The fatty matters of food without undergoing much change, are therefore readily assimilated by the animal organism, and applied when given in excess to the storing up of animal fat. On the other hand, substances rich in starch are especially fitted to support respiration. Oily and fatty matters, however, when given with a scanty supply of starchy food, become available for the support of respiration; and again, gum, starch, and sugar, when given to fattening beasts to excess, are transformed into animal fat. There is thus no essential difference between the fatty or

starchy constituents of food in so far as their uses are concerned, but each according to circumstances can lend itself to the work which is the more peculiar province of the other. The proportion of carbon in fatty matter amounts to rather more than 80 per cent., and is much larger than in gum, sugar, or starch. Oil and fat, for this reason, are not only better producers of fat than starchy and sugary compounds, but are likewise more powerful agents for the support of respiration and the maintenance of animal heat—the heat generated in the body being proportionate to the amount of carbon consumed in a given time during respiration. Gum, sugar, mucilage, starch, and a few similar compounds may be represented as consisting of carbon and water only, and on account of the simplicity of their composition they are well adapted to support respiration. The quantity of carbon consumed by the respiration of animals varies at different times and in different species, according to the rapidity of their breathing and their mode of living. Under all circumstances, however, it is considerable, especially in the case of ruminating animals. Thus cows consume four-ninths of the carbon contained in their ordinary daily food by respiration, and throw it off in their exhalations in the form of carbonic-acid gas. Hence the absolute necessity of supplying large-sized animals with abundance of carbonaceous food."

The chemical analyses of various kinds of straw, by Professor Voelcker, form a very valuable portion of his report. It is only the general results of these that I shall attempt to bring together on this occasion; and this I shall do by giving the different amounts of soluble and insoluble matters which the straw examined by the Professor were proved to contain. This was the mode of examination originally adopted by George Sinclair, in his examinations of the different grasses cultivated in the grass garden at Woburn, the results of which are given in his valuable "*Hortus Gramineus Woburnensis*." This mode of determining the nutritive value of different grasses, observes Mr. Voelcker, by ascertaining the proportion of matters soluble in water, furnishes comparative results which enable us to form a tolerably good opinion of the feeding value of straw. Indeed I find that the more nutritious samples invariably produce the largest amount of watery extract. Straw in general he finds varies very materially in its feeding value; and this to a considerable extent is influenced by the degree of maturity it had attained before it was cut, the unripe being the most nutritious, the over-ripe straw the least so. He found in two samples of wheat straw, the one fairly ripe, the other over-ripe—

|                                  | RIPE, OVER-RIPE. |        |
|----------------------------------|------------------|--------|
| Water .....                      | 8.14             | 9.17   |
| Substances soluble in water ..   | 8.77             | 4.81   |
| Substances insoluble in water .. | 83.09            | 86.02  |
|                                  | 100.00           | 100.00 |

In wheat stubble gathered in December—

|                                     |        |
|-------------------------------------|--------|
| Water .....                         | 17.66  |
| Substances soluble in water .....   | 5.83   |
| Substances insoluble in water ..... | 79.51  |
|                                     | 100.00 |

Similar results were obtained from other straws; for instance, in barley straw dead ripe was found—

|                                |       |
|--------------------------------|-------|
| Water .....                    | 15.20 |
| Soluble organic matter .....   | 2.92  |
| “ inorganic .....              | 2.88  |
| Insoluble organic .....        | 77.62 |
| “ inorganic .....              | 1.38  |
| In barley straw not too ripe—  |       |
| Water .....                    | 17.50 |
| Substances soluble in water .. | 12.40 |
| “ insoluble .....              | 70.10 |

Then, again, in the case of oat straw examined in three different states of maturity, viz., when green, when fairly ripe, and when over ripe, the following results were obtained—

GREEN. RIPE. OVER-RIPE.

|                         |        |        |        |
|-------------------------|--------|--------|--------|
| Water .....             | 77.14  | 46.64  | 35.20  |
| Soluble organic mat. .. | 6.29   | 9.06   | 4.42   |
| “ inorganic ..          | 1.59   | 2.30   | 1.75   |
| Insoluble organic ..    | 14.72  | 40.28  | 55.48  |
| “ inorganic ..          | 0.26   | 1.72   | 3.15   |
|                         | 100.00 | 100.00 | 100.00 |

The most valuable of the ordinary straws is that of the pea. This was found to be composed of—

|                               |        |
|-------------------------------|--------|
| Water .....                   | 16.02  |
| Soluble organic matters ..... | 11.28  |
| “ inorganic “ .....           | 2.72   |
| Insoluble organic “ .....     | 67.77  |
| “ inorganic “ .....           | 2.21   |
|                               | 100.00 |

With regard to the nutritive value of bean straw, great indeed is the difference of opinion amongst practical men. If we may judge from the discordant results obtained by Way and by Voelcker, it is probable that bean straw varies very considerably in composition, as influenced by soils, seasons, and varieties. The bean straw of 1860 and 1861 was analysed by Professor Voelcker. He found 100 parts of each—

BEAN STRAW OF 1860.

|                              |       |
|------------------------------|-------|
| Water .....                  | 19.40 |
| Soluble organic matter ..... | 5.69  |
| “ organic “ .....            | 2.31  |
| Insoluble organic “ .....    | 71.20 |
| “ inorganic “ .....          | 1.40  |

BEAN STRAW OF 1861.

|                                |       |
|--------------------------------|-------|
| Water .....                    | 17.75 |
| Substances soluble in water .. | 6.86  |
| “ insoluble in water ..        | 75.39 |

The Professor adds, by way of comparison, the results of two analyses of hay—one well-made clover hay and the other good meadow hay. He found in 100 parts of these—

| CLOVER. MEADOW.      |       |    |       |
|----------------------|-------|----|-------|
| Water .....          | 20.50 | .. | 16.66 |
| Soluble organic mat. | 18.07 | .. | 17.79 |
| “ inorganic “        | 4.43  | .. | 4.37  |
| Insoluble organic “  | 54.38 | .. | 57.78 |
| “ inorganic “        | 2.62  | .. | 3.40  |

The general conclusion to which the Professor arrives, from the results of his laborious and valuable researches on straw, of which I have made but a very small abstract, are these (to give his own words): “Assuming the land and climate to be equally well adapted for producing in each case, and the crops to have been harvested in the same stage of maturity, I am induced to place the different kinds of straw in the following order, beginning with the most nutritious, and ending with the least valuable for feeding purposes:—

1. Pea haulm.
2. Oat Straw.
3. Bean staw with the pods.
4. Barley straw.
5. Wheat straw.
6. Bean straw without the pods.”

From careful researches like these, the young farmer will rarely fail to derive valuable materials for his profitable consideration. The very varying value of the straw of the same cereal, according to its unripe, ripe, and over-ripe state, may, in this period of extending stock keeping and increasing demand for food, lead him to make sundry valuable calculations; and this differing value of the different kinds of straw may in some instances have a considerable influence in the selection of his rotations. In any case he will arrive at a wise conclusion if he is convinced that there are valuable observations yet to be made, chemical researches of an increasing value, even upon a green blade of grass or a golden straw, which will continue to profitably excite the curiosity and reward the studies of the agriculturist.

### Manures for Grasses.

A thick carpet of such fine grasses as are seen in our old and rich lawns, is one of the most beautiful crops that can meet the eye. The great variety of species which are found in the best pastures flourish on the same spot for centuries, and grow without much or any care bestowed upon them by man. It is, generally speaking, only first or second class land that yields good permanent pastures. All the best and most nutritive grasses soon die out when the soil is poor and unsuitable. This in many cases does not seem to arise so much from an actual

deficiency of nutritive matters as from a certain condition of soil which does not maintain the roots in a healthy state. On a great many descriptions of land, the application of lime has a wonderful effect in lending vigour to worthless and worn-out lands when all other applications have comparatively little. One of the functions of this agent appears to assist in the healthy decomposition of the accumulating vegetable matter.

When inferior pastures arise from an actual deficient supply of mineral matters, such as phosphate of lime, the application of bones is well known to produce favorable results. The use of bones has been the right arm in increasing the productive powers of our rotation pastures, though, for obvious reasons, the effects are now usually much less marked on these than on turnips.

In the manuring of grasses and turnips with phosphate, a few well-marked characteristics of these crops ought to be kept in mind as guides to the economical use of the substance. The grasses in an old pasture field, or even those of the young layers of any of our rotations, have an ample staff of roots running through the soil. These are already in contact with the earthy food of plants, and can much more easily take up what they require than a plant like the turnip, which has all its roots to form, must grow fast, and meet with a corresponding liberal supply. This is the secret of the magical effects which a dressing of superphosphate often has upon young turnips. We have sometimes to dress liberally with phosphates or superphosphates, for the turnips, even when there is abundance of the fertilizing ingredient, to which they owe their efficacy already in the land.

It is quite different with our grasses, natural or artificial. By the permanent mass of roots which they leave in the soil, they can grow luxuriantly when the supply of phosphates is much more scanty. For this reason it is seldom that phosphates or superphosphates can be economically used either for pasture or hay, where the land is under a regular rotation. What of these substances remain, after the demands of the turnips and succeeding white crop have been satisfied, are usually far more than sufficient to produce full crops of grass, if nitrogenous manures are only used.

For these reasons, there is scarcely any crop to which nitrates or manures containing ammonia can be used with greater certainty than to grasses. Their roots, being thickly studded over the land, readily absorb these soluble manures when broadcasted over the surface. The very fact of rapid growth succeeding such application shows that the plants are obtaining a supply of the earthy matter they require.

The comparatively moderate price of the nitrate of soda of late years has caused it to be much more generally used for the grasses than

formerly. From one-and-a-half to three cwts. per acre is the common quantity applied. Where either the common or perennial ryegrass largely predominates in young layers, nothing will send up such a heavy crop as nitrate of soda. The best time for its application is just when vegetation has made a decided start.

On the other hand, when the red clover plants are more plentiful, Peruvian guano, which is less soluble, and comes more slowly into action, is usually considered better suited than nitrates. Autumn dressings of guano often strengthen the clover plants and make them keep a vigorous hold of the land. Guano, too, should be applied sooner in spring than nitrates in all cases, especially where clovers abound.

Red clover is a much slower growing plant than either Italian or common ryegrass. It does not, therefore, make so good a return for applications of nitrogenous manures. And, besides, while grown as a mixed crop, the true grasses sometimes rise so rapidly with liberal manurings that they often overtop and weaken by their shade their slower growing rivals. Were clovers grown alone they would be far more grateful for nitrogenous manures, but, being usually mixed with ryegrass, they are not placed upon an equal footing. This is all the more apparent when nitrates are used for a well mixed layer of grass seeds. In this case a full and well mixed crop of hay may be drawn up, but the clover roots are far more exhausted and less fitted for producing an aftermath than when guano is applied.

It ought always to be kept in mind that there is no special unfitness in clover for being benefitted by dressings of nitrogenous manures. Clover and ryegrass, as usually grown, have merely different capabilities for digesting or assimilating a certain amount of nitrogen in a given time. The difference in this respect between red clover and Italian ryegrass, which may be taken as representatives of two different families of plants, is not nearly so great as betwixt these two and other individuals of their respective families or orders. It is only a few of the many hundreds of grasses that respond to liberal treatment, and are therefore fit objects for cultivation. If a rich old lawn is dressed richly with nitrogenous manures, a few species grow up before all the others, and keep them out of view. Indeed, as in the animal so in the vegetable kingdom, each species has a limit or capacity of growth which cannot be exceeded. We have long ceased to look for the plants which will grow without manure, but, instead, for those which in some measure act the part of gluttons, and at the same time give a good account of what they are supplied with. No plant can, perhaps rival Italian ryegrass in this respect, for, when supplied with moisture and manure, it grows almost uninterruptedly throughoutspring, summer and autumn.—*Scottish Farmer.*

### The Earthworm—Its Use.

Reaumur calculated that the number of worms on the earth exceeds the grains of all kinds of corn used by man, and as, perhaps, there is in other animals so preyed upon without any diminution in numbers as the earthworm, the calculation may not be far wrong. Hedgehogs, frogs, and moles devour it; beetles pray upon it, and often *cast* their young on it—and but for the earthworm a large portion of the bird family would soon deteriorate or perish, for, with the exception of the finches, there is scarcely a bird, from the robin to the wild-goose, but eats it, and many, during open weather, live almost solely upon it. After a summer shower, the farm-yard ducks actually race against each other along the roadsides in search of it; and on wet days they each devour hundreds. All river fish feed to a great extent upon it; and wherever the river beds are of a clayey substance, worms are more plentiful than in *terra firma*.—The river worms are darker in colour and flatter as a whole than the earthworms, but so little do they differ in appearance that a novice could not tell the land from the waterworms. The worms in the water live under the embedded stones, and trout are generally on the watch to gobble them whenever they leave their abode; they even move and turn over the stones in search of worms and the larvæ of water flies.—When a flood comes, the stones are generally displaced in great numbers, and at such a time (in a river such as the Tweed, for instance) the worms must be dislodged and carried along the river bottom in tens of thousands; and it is for such food, too, that ducks are constantly *gumping* among river shallows; for, if watched, it will be seen that they insert their bills below, or move, mostly all the likely stones they pass. We have frequently turned up worms at a depth of about one foot in the rivers.

But though the worm yields a considerable amount of food to the birds and fish that grace the dinner table, it is much more beneficial to man as a fertilizer of the land. Subsisting on the earth through which it burrows, with an occasional meal from a decaying tuber or leaf, its pecculations from the husbandman are of the smallest nature; whereas it lightens "the earth's surface" by its burrowings, and thereby aids the spreading of the roots of all cereals and bulbs; and the burrows also carry down water after heavy rains, that, but for them, would often gather in surface-pools, and thereby injure the crops; and they also admit the air to the soil to a depth by which by natural means it could not reach. The earth ejected by them also tends to the improving of the soil; and instances are known whereby these droppings or "worm casts" caused in a few years, a considerable increase to the depth as well as the quality of the soil. Mr. Darwin, the naturalist, gives

an account of a case of this kind which he tested, and from experiments he clearly proved that, in an old pasture, a layer of cinders and lime had been covered within a few years, to the depth of an inch, by the castings of worms. "On carefully examining," he also wrote, "between the blades of grass in the fields above described, I found scarcely a space of two inches square without a little heap of cylindrical castings of worms." Now, a week or two ago we chanced to walk through an old pasture, and we were much struck by the number of the worm-casts it showed. They were, we are certain, nearly, if not as numerous as those mentioned by Mr. Darwin, and they darkened the field so much, though the grass was growing, that the caused some parts of it to look as if newly top-dressed. And when the fine soil thus raised gets spread by the feet of sheep or cattle, we doubt not but a stimulating top-dressing it will make. We have since examined several old pastures, and the castings were numerous in each; but we noticed that they were fewest on the pastures where lime had been most used. This we set down to the hurtful effect that lime will be likely to have upon the wormlings.

The earthworm is in more cases injurious to the gardener than the farmer. The giant lob-worm occasionally carries the main leaf of a young plant bodily into its hole; and in gardens, the bareness of the soil enables the observer to notice that it is a common thing for worms to drag straws, grass blades, plants, leaves, &c., into their holes; but for what purpose these are carried down nothing definite is known. The things taken down, however, pass into manure.—The worm in the garden has its uses if it has its faults; and when it partakes of "green meat," which it never does extensively, the food selected is generally some vegetable or root rendered soft by decay.

They do not penetrate the soil to any great depth, because they require air. In stiff soils they are not generally found much beyond a foot from the surface, but on lighter soils, through which they bore with more ease, they may be found deeper. At all events, they go deep enough to permeate the soil, and air and drain it, at a depth to which the plough cannot reach, and for which, we fear, they get but little credit. Indeed, their usefulness is seldom thought of, whereas by many they are still ignorantly looked upon and loathed as the

"Wriggling tenants of the grave."

—*Scottish Farmer.*

Liebig estimates the amount of nitrogen abstracted per acre by the hay crop at 56lbs, equal to 104lbs of ammonia.

The hay of red clover, cut in full flower, 25th June, contained of water 16.60, of ash 5.90, of woody fibre 31.37, of nutritive substances 46.07 per cent.

Illinois State, at Peoria, September 29 to October 4.

**FLAX SCUTCHING.**—The Flax Scutching machine lately imported by the Government and presented to the Board of Agriculture of Upper Canada, and of which an account has already appeared in this journal, was submitted to a trial, experimentally, in Toronto a few days ago. A number of gentlemen interested in the production of Flax were present, and were satisfied that the machine will prove a most efficient implement, and will be the means of saving a large portion of the expense heretofore incurred in the preparation of the fibre for market. Parties who have flax on hand which they wish to have scutched may obtain the use of the machine by application to the Board of Agriculture, and paying the necessary expenses. At present it has been sent to Newcastle, West Durham, to dress a quantity of flax on hand there.

### Cultivation of Flax in Canada.

#### *Meeting of the Belfast Linen Trade.*

Yesterday a meeting of the linen trade was held in the council-room of the Chamber of Commerce, to hear a statement from Mr. Donaldson, Agent of the Canadian Government, regarding the capabilities of Canada for the production of flax, and the facilities which exist there for its successful cultivation. Wm. McMaster, Esq., was called to the chair. The other members present were, Messrs. John Hind, John Cuddy, E. H. Thompson, W. Mitchell, J. Wallace, W. H. Patterson, Wm. Crossley, Henry Dickson, Charles W. Shaw, W. McIlwrath.

**CHAIRMAN.**—I have merely to say that, in consequence of what Mr. Donaldson, the Emigration Agent of Canada, said to myself and other members of the linen trade upon the cultivation of flax in Canada, we thought it advisable to hold a meeting and hear what he had further to say on the subject. We held a

meeting last week, which was attended by a very limited number of the trade, and what he brought before us we considered of such importance to the trade that we thought it right to call another meeting, and let the members decide whether any steps should be taken. The secretary will read the minutes of the last meeting, and then Mr. Donaldson will make his statement for your information.

Mr. McIlwraith (secretary) read the minutes of the last meeting, and the advertisement convening the present meeting.

Communications from Mr. Jonathan Richardson, M. P., and Mr. James Herdman, Strabane, were read, in which these gentlemen stated their inability to attend the meeting.

Mr. Donaldson (who produced and laid on the table several samples of flax, both in the straw and in the scutched state—the produce of Canada) said he had little to add to what he had said before. When in Belfast, last year, he found there was a great demand for the raw material, and that exertions were being made to secure the cultivation of flax in India and other places; and the question naturally arose, could flax not be grown in Canada? On his return to Canada he brought the matter before the Canadian Government, who were well pleased that he had given his attention to the matter here. He visited the various agricultural meetings in Canada; and having gone through various parts of the country, he thought the best thing he could do would be to bring samples of the flax both in the straw and in the scutched state to Belfast. They were now before the meeting, for the inspection of those present. Although the samples were very good, they were not near so good, he thought, as might be produced.

Mr. Patterson.—You have had some of Rowan's machines sent out.

Mr. Donaldson said that immediately when he went back to Canada he had advised the Government to send for a number of Rowan's flax scutching machines, and on his statement of their efficiency, which had been proved in this country, a number were ordered by the Canadian Government. He did not hesitate to say that the soil of Canada was well qualified for the cultivation of flax. It was something like the soil of this country, and the rotation of crops followed generally similar to what they did here. Last year about 2,000 acres of flax had been grown in Canada. His principal objects were—first, to show the merchants of Belfast that in Canada flax could be grown suitable to their market, and, next, to advise the flax merchants of this country to send out some party to give instructions in the production of flax, such as would be suitable. The people of Canada were now considerable consumers of the manufactured article, and the more flax was cultivated there the greater would be its export to this coun-

try and the greater the import of the manufactured article, so that it would be advantageous to both.

The Chairman said, judging from the sample he saw, there was little doubt that flax could be grown, but at what price could it be set down here? Where did the 2,000 acres go which were grown last year?

Mr. Donaldson.—It all went to the United States, except a small parcel that came here to Mr. Preston.

The Chairman.—What was got for the produce generally?

Mr. Donaldson.—I think about £40 a ton. One company that has scutch mills, bought 1,500 acres out of the 2,000; but I am sorry to see that by fire \$40,000 worth of flax and buildings have been destroyed. I am quite satisfied, we can raise an acre of flax or anything else as easily as you can here. The labourers there are better paid for their labour. A man who gets 4s. or 3s. 6d. a day for his labour will, of course, do more work than a man who only gets 1s. 6d. It takes £7 10s. to £10 to raise an acre here, and I am quite satisfied that it can be raised in Canada for £4, considering the cheapness of the land.—One of my objects is to get the manufacturers of Belfast and the province to send a party to Canada to give instructions respecting the proper mode of growing it; and I think, if this be done, the farmers there will adopt the growth of flax more readily. The Government make an offer of paying the passage to Canada and the travelling expenses of the gentleman so sent. A son of Mr. McCrea, of Strabane, with whom the trade are familiar, offers to go for £200 a year, and this expense would be very trifling to the merchants of this province.

Mr. Hind.—For what purpose was the flax used in the States?

Mr. Donaldson.—For canvas and cordage. Mr. Preston, I believe, got £50 a ton for some of what was sent here.

Mr. Hind.—Is there any prejudice in Canada against the growth of flax?

Mr. Donaldson.—None, except it is hard to pull.

Mr. Hind.—It takes eight women to pull an acre here.

Mr. Donaldson.—Four men will pull an acre there, and it is cut as close as meadow—close to the ground.

Mr. Patterson.—A country that could produce this flax could grow flax fit for any purpose.

Mr. Donaldson.—I have no hesitation in saying that, when you are going to such expense in the cultivation of flax, if you give any attention to Canada, you will get a plentiful supply there in a short time. By encouragement you will get as much in two years as you will from other places, I believe, in five

or six. As we increase growing you will increase selling to us.

Mr. Patterson said that a great deal of what Mr. Donaldson had said was much in accordance with his own opinion. He saw an article from Mr. Donaldson in the Toronto Daily Leader, and it was evident that the public of Canada were alive to the matter. He (Mr. Patterson) had written a letter to that paper, and in it said that, if they would grow the flax, the people of Belfast would buy it.

Mr. Hind said there was no doubt that how to obtain a better supply of flax was the most important question connected with the linen trade. Mr. Donaldson's proposition was a very feasible one; but would it be right for them to teach the people of Canada how to grow flax that might be bought up by a competing country?

Mr. Donaldson—Yes; but I am sure you will get the preference.

Chairman—Is there any duty in the States?

Mr. Donaldson—I think  $12\frac{1}{2}$  per cent.

Chairman—That would be quite protective enough.

Mr. Donaldson said at present farmers did not generally sow flax in the best land. He had had a conversation with Mr. McCrea about it, and he was quite satisfied that in Canada flax could be grown equal to anything grown in Ireland. He had not spoken his own opinion merely.

Mr. Hind said they were met to give assistance to this project or the reverse. There could be no doubt at all about the importance of this question to the flax spinners of Belfast, and the country generally, and anything that could give them an increased supply of the raw material would certainly be a great boon to the trade. But it should be remembered that the United States was very near Canada, and that, especially in the States bordering upon Canada, there had lately been considerable progress made in both cotton and woollen manufactures; and, of course, if they saw their way, they would be naturally anxious to advance in the manufacture of linen also. If the people of Belfast subscribed their money for the cultivation of flax in Canada, they might be merely giving encouragement to the manufacture of linen in the United States. He (Mr. Hind) would be glad to see a good supply of flax coming from Canada, or any other place that could supply it, but he had no desire that they should put a whip into the hands of those who should whip them. Let there be a guarantee that some direct benefit would be gained by it. How could they tell whether or not one ton of the flax would ever come here? How could they tell whether or not the Americans would give a higher price? He (Mr. Hind) was afraid the project was not looked on very successfully by the manufacturers of this part of the country, else they would have had a larger meeting to consider the question.

He did not want to take a narrow view of the question; but the linen business had not the elastic nature of the cotton business, and they should be naturally jealous of not letting the trade escape from themselves. If a guarantee were given that a portion of the flax would be sent here to be sold at market prices, the question would be different. There was no doubt the flax could be grown. The question was, should they take any steps in the encouragement of the growth of it?

The Chairman said it could not be expected that a guarantee would be given.

Mr. Donaldson—Of course if the Americans give £50 a ton for it, and no more could be obtained here, I could not secure the flax to you; but I don't think you need fear getting a very large portion of it.

Mr. Hind—We have got none of it yet.

Mr. Donaldson—There were only 2,000 acres grown last year, and very little of it would suit your market. But we can grow what will suit your market, which I don't think the Americans will purchase.

Mr. Hind—But the facility of getting it might easily raise a market in America for it. We have made two or three attempts to force the cultivation of flax, and the very places where we did so we got least from; and it occurs to me that, if the farmers of Canada find it to be for their interest to cultivate it, they will do so irrespective of any assistance from this province. If they did not find it to their interest to cultivate it, they could not be made grow it. If they get a better price here they will send it here. If not, they will not send it. If they can make money by growing wheat they will grow wheat, and if they can make more money by growing flax they will grow flax; and if the Government of Canada are anxious for the growth of flax, £200 a year is not a large matter to stand in the way. I think all we can do is to say:—"Here is a market for you. We will give you all encouragement that a buyer can give a seller if you only bring it to us." But it is not our duty both to pay for the cultivation of the material and then to purchase it.

The Chairman thought they should first see how much of this season's growth would come here. He thought the cultivation was more a Government and farmer's question than theirs. Instead of being beneficial to them it might be injurious.

Mr. Donaldson—Seeing the anxiety on the part of the manufacturers and flax spinners here to get the raw material, and, seeing that you had subscribed towards its cultivation in India, I was convinced that you were anxious to have a large amount of it. If I had not supposed that the proposition would have been met quite heartily, I would have endeavoured to get our Government at home to do something in the matter at once. But seeing that it was easy to grow a large quantity of it here, almost at

your own doors compared with India, I thought the matter would have been taken up very readily. The Government have given very little attention to the matter as yet. The anxiety of parties here for large quantities of the raw material is the very reason I brought the matter so strongly before you.

A Member said that the India flax Company was no comparison. The flax raised by them would be brought there.

Mr. Hind—We are very anxious to get the raw material, for I think the trade was never in such want of it as at present. The flax has only to be sent here to be sold on the very best of terms. If sent here it will be purchased, and I think the matter need not be proceeded with farther.

Mr. Patterson did not concur in the apprehension that the Americans would cut out the trade of this country; but he agreed that the trade here should not go to any great expense in the matter. Let what would be grown this year be sent over, and it would be seen the kind of market it would bring.

Mr. Hind—2,000 tons could be sold before the end of the month if in Belfast at present.

Mr. Patterson—If flax of this sample were sent to this country it would pay freight, commission, and everything, and bring £60—or £65 per ton.

Chairman—Some of us have given £70 for no better.

Mr. Hind begged to move that the matter be adjourned *sine die*. He thought that their offering a ready market nineteen years for certainty out of twenty was great encouragement for the cultivation of the fibre. If the Canadians thought it profitable to cultivate it by finding a good market for it, at the highest prices of the day, according to quality, they would do so. He (Mr. Hind) thought that that was all the encouragement they could give, and begged to move that the matter be adjourned *sine die*.

Mr. Mitchell seconded the motion, which was put from the chair and carried unanimously, and

The meeting separated.—*Belfast Whig*, of May 6.

### The Fat Stock International Show at Poissy.

(Abridged from the *Mark Lane Express*.)

In England we know a great deal about France military, France Naval, France political, but very little about France agricultural. We are well acquainted with the *savans* of literature and science, but very little with the labours of

those whose enlightened researches into the principles which should govern the practice of the cultivator and breeder have produced wonderful results since 1815. We are very familiar with the ubiquitous red shirt of the barricade, but we know far less of the blue blouse of the peasant. The political revolutions which have shaken the land to its centre, are present to our minds in all their frightful and heroic details; but we scarcely know anything of the silent but potent agencies which are at work throughout the fertile plains and mountain regions of this splendid country, producing abundance where once was barrenness, knitting together village to village, town to town, district to district, department to department; connecting the whole, in fact, by iron or macademized ways, with the great ganglionic centres of nervous force—the cities of France. We know but little of the markets which are thus being opened in localities where the population had no inducement to furnish more than their own wants, or, in fact, of the great stimulus imparted by the increasing strenuousness of demand to the energies of supply. The improvements effected since 1815 are scarcely to be credited; and the fact is the more interesting, because what occurred with us eighty years ago is here going on before our eyes. The foreign trade of France has quintupled, her manufactures have quadrupled, her agriculture has doubled its produce, under the influence of those three great principles of peace, justice and freedom, which are the eternal counterpoise to the hateful effects of war, violence and despotism. Eighty thousand miles of road have been opened, ten thousand miles of railway have been completed, canals have been cut, and rivers rendered navigable. Since 1789, 5,000,000 acres have been added to the productive area of the country; vineyards, and orchards, and meadows have increased, while woods have diminished. In tillage, we possess M. Lavergne's authority for stating that the cultivation of fallows has decreased by one-half; that the growth of wheat, barley, and oats has increased a third; that the water meadows have tripled in extent; and that the cultivation of roots, which was hardly known in 1789, now covers 5,000,000 acres.

We have often heard it stated that we have nothing to learn from French farmers; but the English who are here, and who have the advantage of being able to compare the present Show at Poissy with the Show held upon the same ground in 1857, are generally of opinion that if this is the case, it is equally certain that our French brethren will not much longer require our tuition. The carpet-bag and railway-ticket are fine institutions for settling men's ideas.—Until we visit the fair, we fancy we are masters of the best horse in the country. Nothing will prove of more service to English breeders than this trip to France, notwithstanding that some

were the subjects of an amusing and not particularly pleasant episode on the frontier in coming. "These Royal Agricultural Society of England Show," said a celebrated English machinist, "will be the death of me: I no sooner invent one thing than I must at once begin to improve upon it before the next meeting, or else arrive there to find it superseded and antiquated: there is no rest." Even so: the English breeder will find as little rest as the implement manufacturer, if he is to keep his ground in France; and as this is a most important market for him, we are all the more pains to impress upon him the imperious necessity of straining every nerve to keep the lead he now undoubtedly holds.—The man who wants rest must withdraw from the struggle; to stop, with a crowd of eager competitors in the rear, is to be run over.

The arrangements at Poissy, as compared with those of the Royal Agricultural Society's meetings, merit a passing consideration. How much taste is displayed here! How much prosaic stolidity at home! Here the sun falls upon bright colours, of a pretty vandyked valance hanging from the eaves of the waterproof shedding, and flags, tastefully grouped, flaunt gaily in the breeze; a coat of paint is bestowed upon the wood-work; all, adding about five per cent upon the total outlay, gives a charming *tout ensemble*. Why not a little more decorative display at Battersea? The last arrivals took place on Sunday. On Monday nothing was done until noon. The animals were then brought from their comfortable stables, and placed according to the official programme. Two juries immediately commenced their labours, the avenues being guarded by soldiers, and no non-official was admitted, save members of the press. One jury judged the cattle classes, the other the sheep and pigs. Both consisted of twelve members and a president. The composition of the first were as follows: Five landed proprietors, two Government General Inspectors of Agriculture, an Inspector General of the Imperial Veterinary Schools, the Veterinary Professor at Alfort, a member of the central School of Agriculture, a Professor of Zoology, a Paris butcher, and last, though not least, our own Mr. Fisher Hobbs, who had no little difficulty in swaying the predilections of the last-named member of the corps. The second jury was similar, and both contained many men who were more disposed to rely on the old butcher's opinion than on their own.—So far as we observed, the presence of this professional worked well enough, and we see more reason than ever to urge the adoption of the same practice at our Christmas Show. There is but little dissatisfaction with the awards; it is only here and there, where the French taste for the round has overruled the English taste for the sirloin, that there is any fault-finding.

The following is a synopsis of the entries:—

## BRITISH.

|                                                 | Steers. | Oxen. | Heifers. | Cows. | Total. |

| Ayrshire, &c.....                               | 0       | 0     | 0        | 0     | 0      |
| Irish.....                                      | 1       | 0     | 0        | 1     | 2      |
| Other breeds.....                               | 0       | 1     | 0        | 0     | 1      |
| Cross-breeds.....                               | 3       | 3     | 2        | 0     | 8      |
| Cattle.....                                     | 16      | 12    | 13       | 16    | 57     |

There were no entries in the Leicester, Cheviot, Blackfaced, and Mountain Classes, Dutch, Belgian and German Classes. In the Long-wool Classes there were 4 entries; in the Southdown 3; other short-wools 3; Kents 1; Cross-breeds 2; total 13.

The entries in the Pig classes number 25.

Altogether there are 95 entries of British stock, from 41 exhibitors.

Mutton is now more an object in France than wool, or, at all events, than the short-wools which are supplied by the Australian colonies at such a rate as to discourage the French growers.—The merinos are crossed with the Dishley's, and the current is now turned in favor of long wools, as well as mutton, as may be seen in the award of the prize of honour to the Cotswold breed, 7 to 3 making a decision which a few years since would, notwithstanding the huge proportion of the Cotswolds, have favoured the Downs.

The pig in France thrives better than it does with us. A dry soil and warm climate are more conducive to its development; and our own pigs do much better in the Gallic than in the British sty. It is said, on good authority, that the best breeds of France are descended from ours, and that therefore Nature helps them to beat us with our own weapons. These facts will prepare the reader for the announcement that England does not hold the pre-eminence in the porcine breeds that she does in the ovine and bovine. Our neighbours seem certainly to have a better idea of tenderness in pork than of that quality in either beef or mutton. Our show of pigs is still creditable, and the credit is due to Mr. Waters whose 17-months Sussex, weighing 30 stone, bears off the medal of honour in the pig classes; and Mr. Crisp supports his own as well as the national credit in the 4, 8, and 18-months classes, receiving one 1st and two 2nd prizes.

In the following notice of the French stock it will be best to follow the course indicated in the programme. As a tabular statement may also prove convenient we append one:

|                                               | Steers from<br>3 to 4 years. | Oxen. | Total |

| Limousine.....                                | 3                            | 13    | 16    |
| Garonnaise and Baza-<br>daise.....            | 8                            | 18    | 26    |
| Other Breeds :                                |                              |       |       |
| Large.....                                    | 6                            | 15    | 21    |
| Small.....                                    | 5                            | 20    | 25    |
| Shorthorns.....                               | 7                            | 6     | 13    |
| Other Foreign Breeds..                        | 2                            | --    | 2     |
| Crossbreds.....                               | 44                           | 31    | 75    |
| Cows :                                        |                              |       |       |
| French Breeds.....                            | --                           | --    | 13    |
| Foreign Breeds and<br>Crosses.....            | --                           | --    | 27    |
| Lots of four or more                          |                              |       |       |
| Bullocks.....                                 | --                           | --    | 16    |
| Females.....                                  | --                           | --    | 8     |
| Extra.....                                    | --                           | --    | 4     |
| Calves.....                                   | --                           | --    | 18    |
| Cattle.....                                   |                              |       | 305   |

Of sheep there were upwards of 300 in pens of ten, the entries for merinos and mixed merinos being 8, large long-wools 8, small and ordinary wool 19, extra 3.—Total 33.

Of pigs the entries of French breeds are 32, foreign breeds and crosses 47, crossed French and foreign 14, lots of four or more 7.—Total 100.

Altogether there are 438 entries from 234 French exhibitors.

We purpose to commence this review by stating a few facts relative to the history of the pure Durham breed in France, and the position it is likely to hold, and then to go on to give a brief notice of the specimens of the native breeds here exhibited, and the results which have followed from crossing them with the Ameliorator Durham, and with each other.

It is now about twenty years ago since the Durham was first imported into France. The national establishments, where the breed was first cultivated, no longer now monopolise the credit, for private enterprise is at work to extend it. The course of the Durham has not been quite uncontested with us ; and on the plains of the North-west, where it has made most way, it has had to meet and overthrow several stout antagonists before occupying their places. All this was a work of years ; but our neighbours have been judicious. Liberal bidding at our great sales has placed France in possession of some of the most celebrated names of the English Herd Book, and constitute a stock now registered in a herd book, which, published every four years, has reached its third volume. From the last volume it will be found there are about

143 breeders, and some 1,600 pedigree animals. As to the genuine character of these entries, it is sufficient to state that the French are even more particular in the matter of descent than ourselves—that no animal is received unless an unblemished shield can be shown on both sides ; and the Emperor has lately required that no shorthorn shall be imported into the Imperial herds without the descent can be traced on both sides to the second volume of the English Herd Book. Animated by this elective spirit, the Jury passed at once three steers entered as pure Durhams, into the cross class, because they could not exhibit this double certificate of unexceptionable parentage. Whether the shorthorn is as likely to become as useful as a pure breed, as he is an ameliorative breed, it would, perhaps, be difficult to say ; but, judging from the show here there seems clear reason to think that he will be the most useful in the process of moulding the native races. There are certain qualities in the climate and soil of Yorkshire which bring out the higher developments of the Shorthorn in a manner they are eduved nowhere else ; and comparing the pure Durham of France with the minor specimens which represent the English Shorthorn here, there seems to be a tendency in the former to fall short of the full growth we look for. The fresh importation of English blood will, in fact, be constantly necessary, to preserve the acclimatized breed from degeneration. The Shorthorn is now overcoming local prejudice in the north-west, where bullocks are not worked. The small farmer has come to understand why breadth of chest is accompanied with disposition to fatten. The small bone and enormous development of those parts of the body which yield that meat which is most esteemed, are qualities which are sure to give our pet a popular sway. The breed is found now pretty generally throughout the departments of Mayenne and Maine-et-Loire, where most progress in cultivation has been made ; but is most esteemed because it affords a short cut to a result which otherwise could only be obtained by careful selection, followed up with great judgment for a long series of years.

The prize of honour for the bovine classes rests with the pure Durhams. Nor is this all which distinguishes the high position of the breed.—There are six large money prizes offered on the French side, to the best animals under three years of age, irrespective of breed or weight ; and, save one, these all lodge with the Durham pure, or with first crosses of the Durham with the native breeds ; the Durham-Manceau, the Durham-Breton, the Durham-Normand, and Durham-Garonnaise taking the lead in this race for early maturity. The Durham blood in the cross-classes, which are large, also secures all the ordinary, and, save one, all the supplementary prizes, such as those offered by the town of Poissy. In fact, the strength and interest of

the French cattle lie in this presence of our Shorthorn mettle.

Of our other English breeds, there was only one pure French specimen, and that an exceedingly good Hereford. Now for a word or two concerning the native breeds, which are divided into large and small, workers and non-workers, those raised for their milking, and those for their beef-producing properties. It will only be necessary now to dwell on those which are not due to slight local circumstances, but to those which appear to have a permanent character and a pliable frame.

The Normand or Cotentin extends over five or six departments of the north-west. Two circumstances have contributed to its development—the superiority of the Paris market, and its exemption from work. The small breed yields Isigny and Gournay butter, and the other the meat for the French metropolitans.—This breed produces about one-fourth the meat consumed in Paris, and about as much more consumed locally; or, annually, about 100,000 fat beasts. The bovine population of these departments should be taken at one million head, including 500,000 cows, = 1 head to 7½ acres. The departments round Paris have no special breed, the Cotentin has spread there. It is a red or brindle, bony race, but is capable of improvement with the short-horn. One of the gaunt specimens here stands 5 feet 7 inches; in length, to horns, measures 8 feet 6 inches, and in girth, 9 feet 1 inch; weighs 216 stones, age 7 years 2 months; his ribs being barely covered with coarse flesh, such as one so often gets at the Paris restaurants. Crossed once with the Durham, the size above is reduced, and we get a result like the following: five feet in height, 7 feet in length to horns, 8 feet 6 inches girth, weight 150 stones, age 48 months. Where the Normand has been crossed frequently with the Durham, as is the case of two or three of the cows shown, these results are animals fit for one of our Christmas shows.

The most hopeful native breeds, however, are the Charolaise and Limousin. The Charolaise is a large, expansive, mouldable white bullock, with jutting shoulders, a dropping back, great massive rumps, ungainly set of tail, heavy bone, narrow chest, and mild expressive face. These occupy, with the Lorraine and Comtoise races, the twenty departments, which form the north-eastern angle of France, and contain 2½ million head. When all the country beyond a radius of 50 miles of Paris was considered a *terra incognita*, the Charolaise was mainly used for work; but now that the limits of this radius extend, it is being known more for the value of its flesh than for its patience under the yoke. It has, perhaps, owed its immediate development to its neighbourhood to Lyons; it has extended through Nièvre and Berri, and now furnishes to the Paris Market nearly as much weight of meat

as the Normand. The measurements are as follows: height 4 feet 10 inches; length to horns 6 feet 8 inches; girth 8 feet five inches; age 45 months; weight 900 kilos. The cross with the short-horn reduces the exaggerated defects, gives width to the chest, contracts the shoulder points, sets the tail right, and corrects the drooping rump. Great things are to be done by means of this mixture of blood, and also by infinite pains in the selection of parents without it.

The Limousin comes from the volcanic centre departments. It is one of the working classes; but when taken from the yoke and treated liberally, it becomes a most valuable meat producer. There is much resemblance in form to the Charolaise; but it is rather large, and of a rich cream colour. The elbows are out in some cases about 8 inches, and give the animal a deformed look. Paris consumes annually about 20,000 Limousin beasts, of which two-thirds come directly from the provinces, and the rest after having passed through the hands of the grazier of La Vendée and Normandy. This is the main meat production of the breed; for in the country whence it comes, the folks are too poor to eat meat. Though very good results are obtained by admixture of the Shorthorn blood, it is thought that without any change of this sort nothing would be easier than to triple the production of meat by a better system of culture, by irrigation of meadows, and drainage. The Limousin is much larger than the Charolaise—in height 5 feet, in length to horns 7 feet 11 inches, girth 8 feet, age 38 months, weight 154 stones. The Shorthorn performs the same ameliorative work as in the other case: the back straightens, the cavity of heart expands, and the skin mellows. The Durham-Limousin is in many cases a better animal than the pure aristocrat. Next in order come the Garonnaise, Bazadaise, and the Salers, which generally reminds one of the saying of an acute French farmer: "We excel in producing bullocks for the racecourse, and horses for the butcher." Some of the great red Salers are inches higher behind than they are in front (6 ft. to 5 ft. 9 in.), and their spines hang like a suspension bridge between the two piers, in a great sinclinal curve: these have as yet, their temporary uses. The Manceau is a more useful, thickset breed, and produces a valuable cross with the Durham. We have yet to mention the Chollet, the Mancelle, the Aubrac, the Parthenay, Flanders, and Nivernese, but must leave them for some future occasion. The microscopic Breton, also, covering so much space in the west, now that the Ayr and Durham cross is established, is likely to become very important, because of its quick feeding properties, and its singular ability to make the best of a poor pasture. The native race and its crosses are well represented.

And now we will venture a word or two about the French sheep. France possesses a fair contingent; but still is much indebted to us for the introduction of the Southdown and Dishley blood, which certainly has worked wonders for the flock-masters. The prize of honour lodges with a pen of pure-bred Southdowns, which display great beauty and maturity. The climate, however, induces too much delicacy of constitution, if this can be in any way indicated by the ears. The wool is much shorter also than those of Lord Walsingham's 10 months Downs with which we compared them. The average length and girth of English Downs is 2 feet 6 inches and 3 feet  $7\frac{1}{2}$  inches, the age 10 months, and the weight 327 kilograms. The French 12 months sheep weighed 342 kilos., measured in length 2 ft.  $2\frac{1}{2}$  in., and girthed 3 ft. 5 in.; the wool on the former being 2 in. long. It seems as though the same reasons we adduced for esteeming the Shorthorns as more valuable in France to mould other native breeds, than to exist alone, might apply to the Down. The climate of France is certainly well adapted to them; but they will require a pretty frequent importation of our blood to keep them vigorous. The result of crosses here shown with the Berri sheep are exceedingly good. The first of the show on this side is presented by the Dishley Merinos. The Merino was introduced into France by Louis XVI., for the increase of wool. The result has been enormous; but now that the Australian Colonies are cutting the French out of the market for short wool, and mutton is becoming more valuable, a cross of the greatest value has been obtained. A lustre wool has been reached, and a vast increase of mutton. We have here the improved Rambouillet Merino and the Dishley Merino. No contrast can better show how these creatures are as clay in the hands of the potter. The Cotswolds with Berri sheep give a very fine quality sheep. There is no necessity to mention the rabbit-eared Larzac or the calf-headed Vendeans; but of the silky-woolled Mauchamp breed, the result of a mischance ably handled, and of the Charnoise, the result of a chance cross between a Berri sheep and English ram, it must be said that they produce the highest qualities, and are worthy of careful development.

Of the pigs we have already said that of the French and British classes, we come to the general conclusion that, although our neighbours have advanced at so surprising a rate since the last Poissy Show, they have done so by handling the means we have given them in the most skilful manner, and that, if they could continue to progress, they will still be continually obliged to resort to us for new blood. There are some physiological considerations in connexion with this conclusion which cannot now be touched upon. While we are careful to keep the lead, there seems to be a strong and steady demand

upon us for pedigree stock of all descriptions' and the more they improve the more will this demand increase.

### The Royal Dublin Society's Spring Cattle Show.

The *Irish Farmer's Gazette* of April 26th contains an elaborate report of the Spring exhibition of this influential and long established Society, which has done so much not only for the Agricultural but the Mechanical and Artistic interests of Ireland. The live stock in point of numbers and quality were quite equal to former occasions, which is a significant and encouraging fact after the past two very unfavorable seasons. In consequence of manufactories being so much engaged in preparing for the International Show in London there was some falling off in the implement department. The tone of the report of this meeting is hopeful, notwithstanding the depression which Ireland experiences in common with other parts of the United Kingdom, from the late unfavourable seasons and the American difficulties.—We make room for the following observations, which will be perused with interest by many of our readers:—

Mr. G. W. Maunsell said it became his duty to call upon his colleague, Dr. Steele, the assistant-secretary to the society, to read the prizes that day bestowed upon the successful competitors. Taking the present show as a reflex of the enterprise, industry, and prosperity of the country, they had no reason to fear that its future agricultural prospects would not be everything that its friends could wish. Extraordinary advantages had accrued to all sections of agriculture by the way in which the society's shows had been fostered and carried out for many years. As the interest of Ireland in them had increased, the energies of the Royal Dublin Society had been taxed to no small extent to provide accommodation. For many years they had lived, it might be said, in temporary sheds; but they were now enabled to hold their shows in a noble hall, which during the last twelve months had been the scene of an exhibition which did credit to the national industry and taste, and which had been visited by the heir apparent to these realms, and also for the last time by the illustrious Prince who presided over the society. That exhibition had scarcely closed when the increasing wants of the society drove them to extend their premises in a new direction; and they had hardly by the removal of some houses and masonry been enabled on this occasion to give the

exhibitors a foretaste of what they might hereafter expect, when the means of the society, strengthened, as he trusted they would be, by private enterprise and by public aid, should be enabled to carry out the design so ably set on foot by Sir Richard Griffith, by opening what might be called Griffith's Court, which would double the extent of accommodation at the command of the society—and not before it was needed—to the great advantage of the agricultural enterprise of Ireland. Turning from the cattle to the exhibition of implements in the lawn, it was cheering to see the enterprise there displayed, and to think how rapid had been the progress in that department. Every year had brought forth new items of farming implements, which did credit to those who sent them there without price. It was not many years ago since this branch of farming industry was, he might say, wholly unknown. Year after year the enterprise of those engaged in the manufacture of farming machinery had been devoted to continued efforts to produce articles at once the most solid in their nature and the most simple in their detail; and those who looked at the lawn that day would see how ably those conditions had been fulfilled. Without attributing perfection to them, those implements reflected the highest credit on the skill and industry of those engaged in that department (hear, hear). Of late years the value of artificial manures had through the light of science and chemistry been more fully appreciated than before. On the table was a beautiful cup, the gift of a gentleman who was one of the earliest promoters of farming manures—Mr. Lawes. To him and to Professor Hounslow they owed the introduction of super-phosphates in agricultural manures, the results of the use of which might be counted, he believed, by hundreds of thousands. The stock exhibited at the shows of the society did not come solely from metropolitan districts, but was furnished by all the districts of the country. The midland and the southern counties contributed as well as the rest; the Kerry cow was giving way to the short-horn; and two of the highest prizes had been carried away by a Kerry gentleman for stock of the short-horned breed, which half a century ago was probably unknown there. Mr. Bland was one of the successful competitors from the Queen's County; there were Mr. Richardson and Mr. Young from the north; and from the south he might also mention the Marquis of Waterford. One name he would not pass over in silence, for when they considered that the judges, Englishmen, and unconnected with Ireland, had awarded the blue ribbon of the society to the honoured name of George Roe, they had a right to feel proud of the city of Dublin. Donnybrook—(laughter)—had covered itself with glory. Donnybrook had taken the palm from Meath and Westmeath, and while honoured names from these counties

were to be found in particular classes, no less than two of the beautiful cups which were now displayed before them had been borne away by the Donnybrook farmers. Long life and honour to a gentleman who, having worthily illustrated a career of commerce in that city, stood forward now as one of the most honoured and worthy competitors in the race of agricultural industry.

His Excellency the Lord Lieutenant said—My lords and gentlemen, if I may assume that the consent to this motion which the noble earl anticipated will be given, I now beg to return my sincere thanks to this numerous and distinguished meeting for the honour they have just been pleased to pay me (hear, hear). And I can assure you it is with more than usual satisfaction that I find that I need not depart on this occasion from that uniform strain of compliment, and congratulation which it has hitherto been my happy privilege to address to the members of the Royal Dublin Society at the period of their annual Easter meetings. For I will own to you that I was not without some degree of misgiving on this subject. I knew that the recent cycles of seasons through which we have passed have been of the most trying and unpropitious character. In the year 1859 there was a feature which has certainly since been very amply—too amply atoned for—there was a prolonged absence of rain which materially injured our pasture. In the years 1860 and '61, I need hardly remind you, there was a great excess of rain, which did infinite damage to the country—which covered our plains with inundations not yet wholly subsided—and which added a severe scarcity of fuel to the diminished production of food. Of course, these results could not take place without occasioning much partial distress. I naturally should not think of entering now upon any controversy as to the extent and amount of that distress. Most trying it is, indeed, to those who are entrusted with any discretion or responsibility at such periods to refrain from having to resort to the most obvious and immediate methods of relief; and I believe there have been—and till very lately have been—conditions of Irish society in which there might have been an overpowering necessity for applying the most artificial and blundering methods of relief. The land was to a great extent divided between a proprietary and a pauper peasantry. But now, except in very rare instances, it is in the district in which it is effected by the persons who are themselves interested—it is by spontaneous and independent effort that the struggle is made, and for the most part made successfully (applause). Of course, we must still reckon upon encountering the occasional rigour of the seasons, just as in the sister countries probably still wider ravages are being now inflicted by the shocks of foreign conflicts and the stoppage of raw materials. But I trust it will prove to be with the passions and wrath of man as we

know it will be with the strife and turbulence of the elements—since Nature is always found to restore her own excesses, and in different periods to maintain her own averages (applause). However, I entirely agree with the general bearing of the remarks which have been made by the Earl of Clancarty—that, whether we look to the geographical position of Ireland, or to the character of her soil, there will be always such a prevalence of moisture and humidity as will make pasturage, and the production of animals, the most secure and remunerating form which our national industry can assume. I do not, of course, mean, as I am sure he did not mean, or no friend of Ireland could mean, to disparage tillage, or the proper production of corn crops in those districts which are by nature suited for them (applause). Those districts abound in Ireland, and more especially is this the case with regard to oats. But still, coupling the physical condition of the country with the close proximity of those large English and Scotch markets where there is such a vast consumption of meat, I believe that providence has mainly appointed Ireland to be the mother of flocks and herds, and I, consequently, believe that she will fare all the better the more truly she keeps to her natural vocation (applause). And in this useful and patriotic path no more salutary or efficient encouragement can be afforded her than is supplied by those annual exhibitions, coupled with those of the Royal Agricultural Society—these annual spring exhibitions which take place under the auspices of the Royal Dublin Society. These exhibitions, within the comparatively short limits of my own experience, have evinced a most remarkable progress. It is within these limits that you have housed your cattle, and we hear that in another year you are likely to roof your implements. I need not point out to you what an interesting and suggestive exhibition the implements collected in your yards to-day furnish to you, or ever how wide an extent of usefulness they range (hear, hear). The facility of transport, to which we are indebted to our railway friends, has done an infinite deal in promoting every kind of agricultural competition; and we read now, too, of international exhibitions. The Emperor of the French has, with great sagacity, instituted them in his capital; and I am sure we shall be glad to find that one of our most well-known exhibitors, who has obtained a prize in the competition of to-day, not content with the laurels he gathers in your show—I refer to Mr. Ball—has carried away the prize for heifers in the capital of France (hear, hear). I need not say how entirely I agree with the reference which Mr. Napier so aptly made even to the superior care and anxiety which we owe to the permanent welfare of those labourers who, in fact, really furnish the national wealth, which it should be the object of this exhibition to promote (applause). We know that in the last twenty years, notwithstanding any of the draw-

backs and vicissitudes to which I have referred, and of which we lately had experience, yet the stock of Ireland has increased in value within that period from twenty-one millions to thirty-three millions (hear, hear). And with respect to quality, I think it is very probable that almost the worst animal in the yards to-day was as good a one as the prize animal of the same period back. I trust earnestly, my lords and gentlemen, that the varied accidents of these exhibitions, the numbers by which they are attended, the patronage by which they are honored, the skill by which they are fostered, may all progressively advance. It is true that we cannot warm our skies with unclouded sunshine, we cannot mature our crops, we cannot guard our sheep and cattle from all kinds of diseases; but we may continually furnish fresh aids to man in the struggle which he must always have to keep up with nature, giving the largest command over her bounties and making difficulties themselves the spurs to his industry and the elements of his success (loud applause).

### Horticultural.

#### Spring Exhibition of the Toronto Horticultural Society.

We can only afford space for a very general view of the first seasonal show of the Toronto Horticultural Society, which took place in the Music Hall, May 29th. The number of visitors, particularly in the evening, was large, and the display of flowers, fruits, and vegetables, considering the unfavorableness of the season, was extensive, and, upon the whole, of excellent quality. The arrangement of the articles betokened both taste and skill, a department that was undertaken, we understand, by Messrs. Gray and Humphreys, and the efficient pains taking Secretary, Mr. J. C. Small.

Some of the Fuchsias were large, of good form and rich in flower. The collection of Geraniums was extensive, not large specimens, but the inflorescence was varied and beautiful. In foliage plants the show was characterised by a number of luxuriant specimens, some of them new and of very rare excellence. There were also several good specimens of orchids and stove plants, which attracted much attention. These and other rare productions were from the conservatories of Mr. Justice Morrison, Judge Harrison and C. S. Gzowski, Esq. The Petunias were generally good, particularly the finely co-

loured double varieties belonging to Mr. Boulton. Verbenas possessed nothing remarkable, and the Calceolarias, perhaps not above the average of former years. Mr. James Fleming had some very beautiful specimens of pinks and tulips,—and his artistically combined bouquets commanded universal admiration. In consequence of the backwardness of the season, the roses were but few and mostly indifferent,—Mr. John Gray's usual rich collection being absent, was a marked falling off of the show. The vegetables were as numerous as could be expected, considering the drought and cold that has prevailed for several weeks, their quality generally denoted skilful culture.

There can be no doubt that the Toronto Horticultural Society has been largely instrumental in improving the taste and increasing the domestic comforts of a large number of people—the occupiers of the cottage and the stately mansion—and we trust that it and other similar organizations throughout the country, will continue to receive increasing support.

The following remarks were made by the Judges, Messrs. D. Murray, C. Meston, and W. Hill, of Hamilton, in their Report:—

"The judges, while they think that the entries are not so numerous as might be expected, are highly gratified with the exhibition, and discern unmistakable signs of progress. They would specially notice as worthy of recommendation:

"In the Floral Department, the whole of the stove and greenhouse plants, including many rare and well-known specimens.

"The two collections of orchids, Nos. 10 and 49, these they consider the great distinguishing feature of the exhibition, including, as they do, some of the rarest and most beautiful of this class, and forming without doubt the best collection ever exhibited in this Province.

"The fancy geraniums exhibit signs of careful cultivation.

The foliage plants would be worthy of a place in any exhibition. Some of the specimens are entirely new and most magnificent; amongst a very fine *Cyanophytum Magnificum* is particularly deserving a notice.

The six petunias (No. 88) could not be surpassed in Canada.

"In the fruit department, the collection of apples (No. 106), and the nectarine tree in full bearing (No. 94), are deserving of notice.

"And amongst the vegetables, the asparagus and sea kale are the most deserving."

### Hamilton Horticultural Society.

We had the pleasure of spending Her Majesty's birth-day at Hamilton, on the occasion of the first exhibition of the present year of the Horticultural Society. The day was fine, and all business in the city being suspended, everything assumed a holiday appearance. Having an hour or two to spare before the opening of the show, Dr. Craigie kindly conducted us through the gardens and conservatories of Messrs. McLaren, Kennedy and Brown; gentlemen occupying extensive and highly picturesque villas on the slope of the ridge, or, as it is here designated, the "mountain," and commanding beautiful and extensive views both of land and water. We had time for a mere glance only of these tastefully laid out grounds, most of which, as well as several others in this vicinity, were designed and executed by the late Mr. Mundie, of whose skill and good taste in landscape gardening many places in Canada afford a happy illustration. Whether we look for flowers and fruits under glass or in the open air, these establishments are alike creditable to the skill of the gardeners who conduct them, and the liberal spirit and taste of their enterprising owners. The expense of bringing this rough and stubborn soil into so high a state of beauty and productiveness must have been very great, and the artistic qualifications of those who planned and conducted the operations not less so.

The Show, particularly the floral department, was exceedingly good, but the vegetables raised in the open air were, in consequence of the backwardness of the season, few and inferior. The Geraniums were truly splendid, both as to size and varied beauties of color. The culture of these fine flowers does great credit to the skill and attention of their producers. We have never seen such magnificent fuchsias before on this side the Atlantic as those which characterised this exhibition. Several of them were from 10 to 12 feet high, well proportioned, foliage, like the geraniums, very luxuriant, and the inflorescence rich and varied. Calceolarias were rather numerous and, upon the whole, good; but it was said not quite equal to what the Hamilton growers usually produce. Of foliage plants there were several excellent specimens; and also ferns, both native and foreign. There

was quite a number of apples,—the Baldwin and Northern Spy in particular, looked as fresh and plump as when gathered from the tree.

We were much gratified to observe the improvement made in this enterprising city within the last few years. Its squares neatly and strongly fenced by iron railing, and ornamented by planting and fountains, indicate both taste and comfort; while the city commands an inexhaustible supply of the pure water of Lake Ontario, both for public and private purposes. In the evening we went over the well-managed nursery of Messrs. Bruce & Murray, who have a good general stock of trees—fruit and ornamental, and flowers. The day was spent in very agreeable and improving intercourse with the intelligent and energetic horticulturists of Hamilton; qualifications of which our readers must be well aware from the valuable articles which frequently appear in our pages from the members of the Horticultural Club.

### More about Dwarf Apple Trees.

FOR THE CANADIAN AGRICULTURIST.—It appears that my remarks made on Dwarf Apple Trees has awakened Mr. Arnold's indignation. It seems he lays the cause of my not succeeding in growing the dwarf apple trees to being deceived in not getting the right kind of trees. If this is the cause it is what we complain of, hence we cry *humbug*. But if it is my ignorance in not knowing how to manage them I had better take lessons to understand the business. However, I have kept up a continual warfare, in pruning, cutting back, pinching, and nipping, but all to no purpose. But I have not cramped their roots in a pot yet, as we do some plants to make them flower, which perhaps Mr. Arnold will say will be necessary. But in spite of all my cruel treatment they are now out of reach and no doubt they are glad of it. Now, sir, I thought from the description given that dwarf apple trees were so by nature and not by artificial means. If not, it is time their character was better understood. Now I do not say that there is not such a thing as a dwarf apple tree as described, but unfortunately for me I have not got them yet.

Are not all small stunted trees Dwarfs, and have not the nurserymen a peculiar faculty of making them so, for the purpose of fulfilling their desired object? But when they get good cultivation will they not grow as large as any other trees? I believe that most of the dwarf apple trees are of this character. Is this not *humbugging* the people? Yes, and I am not willing to see my brother farmers imposed upon,

as I have been, any longer. I expect to meet the disapprobation of the nurserymen; I have counted the cost and am now paying it.

Mr. Arnold next accuses me of losing confidence in my Rochester nurserymen. True, most true, hence we cry out "*humbug*." But I would have friend Arnold to know that I have not had all my trees from our neighbors, for amongst my first getting I sent to Toronto, to some of the Canadian nurserymen that Mr. Arnold boasts of for their honesty, for dwarf trees and some paradise stocks. Their stocks I grafted myself. Guess I know where I grafted them and can show it to be above the ground too. Now their trees are amongst some of my largest that I complain of. Well might the nurserymen smile, when they can sell hundreds of dwarf trees artificially made to the ignorant public, without the least hesitation of conscience. Now let me remark when I wrote my essay in '58 that some of the early bearing kinds had just began to bear. Thinking from this and the recommendation that they would all follow suit next year, I therefore spoke in very high terms of them, for I was completely in love with them. And I still would recommend every man to fill his garden with them, for they make beautiful low trees, such as I am so much in favour of. But don't expect that you will gather fruit from these trees when they are 2 or 3 years old, or the size of currant bushes, lest you be disappointed. Let us hear what friend Atkins says. If he wanted more dwarf apple trees he would as soon graft them on the common apple stock, believing from his experience that apples on the Paradise stock neither bears quicker nor makes smaller trees than on the common stocks. But if Mr. Aitkins and myself have been deceived in getting the right kind, as Mr. Arnold surmises there may be a possibility of, there we had better begin again. And I hope that Mr. Arnold will take pity on us, and send me 25 genuine trees (payable when they prove to answer his description). I do not know where else to find them, as I have tried many other places and this will be the best proof to his argument. I am sorry Mr. Arnold did not answer Mr. Beadle's requests, for it might have saved those severe strictures he complains of. But extreme cases require harsh medicine. Of friend Atkins' mild remarks there was no notice taken, I suppose because there was no *humbug* in them, for certainly his experience and mine are very much alike. Mr. Arnold invites me to visit his trees and there I will see trees three or four years old and 2 feet high in bearing. I would willingly accept of his invitation if possible, for I would not mind going a hundred miles to see a bush of the Northern Spy or St. Lawrence in full bearing at that size as a common thing. But again let us notice Mr. Arnold's concluding remarks. He says he will show me bushes ten years old that have now heads from 20 to 35 feet in circumference. Now I think it

is plain to be seen that his bush is just like mine; it is a very large one. Few trees will grow bigger in that time. Look a little further when that bush is twenty years old, and keeps on growing accordingly, it will measure 70 feet in circumference; quite a modest little bush, to have many of them in a garden to raise vegetables amongst. Why it might almost be called a mammoth tree, instead of a dwarf bush.

Now, Mr. Editor, I have much respect for these nurserymen, for they are doing much good in improving the county. I like to visit their nurseries, always feel myself at home with them. But, like myself, they work better for a little watching. Friend Arnold must try again and get his dwarf trees a little smaller, and extricate himself from his own trap that he has fallen into. Come and visit me and my fine trees, and Mr. Editor with your indulgence and patience we will fully investigate the character of the dwarf apple tree.

R. B. WERDEN.

Pictou, Prince Edward County,  
May 6th, 1852.

[The above subject is an interesting one, and we willingly admit communications upon it. We trust, however, that any discussion which may arise upon this, or any other topic, will be conducted in none other than the most friendly and courteous tone. We are sure our correspondent does not mean anything else, although some of his expressions may seem a little harsh. A word to the wise is sufficient.—Eds.]

### The Rose.

In a short time the first instalment of Perpetual roses will be due. Universal favorite as the rose is, it requires no recommendation. All the varieties are beautiful, but other things being equal, the Hybrid Perpetuals and the Bourbon, China and Tea Roses are to be selected on account of their more frequent periods of bloom. The Perpetuals are, however, by no means true to their name as regards their bloom, for they flower but twice in the season; profusely in June, moderately in September or October. There will be occasionally a plant which will afford a few flowers at other seasons, but the above is the rule.

Where there is a good cellar, green-house or frame, in which tender roses (under which head China, Bourbon and Tea Roses are placed) can be kept during winter, they are probably the most useful and satisfactory classes, as they are more constant in bloom and of a more delicious fragrance in general.

There is one very serious drawback to the cultivation of roses and that is the great depredations made upon them by the insects. The effects of these attacks are to be seen in the destruction of the tender shoots and buds, and the disfigurement of the foliage, which will have all the tender portions eaten out, leaving only the skeleton and a slight tissue of a dry nature, presenting the appearance of having been scorched. This is almost universally the case with the rose where no precaution has been used to prevent the ravages of the rose slug. The best preventive of its depredations is found in the use of whale oil soap suds, made with two pounds of the soap in fifteen gallons of water, and applied to the foliage with a watering pot, or preferably with a syringe, by the use of which the under side of the leaves may be drenched. The whale oil soap is not a common article of merchandise, but may be procured of the seedsmen in our large cities at a trifling cost.

Where this cannot be procured, a decoction of tobacco will be found a very good remedy. The frequency of the application depends upon circumstances; usually three or four times in the season will be sufficient, but if the slugs are numerous and continue their operations a long time, it must be applied more frequently.

The rose is generally grown singly, though many prefer making beds of the different sorts. Most roses will bloom better if rigorously pruned very early in the spring, but some sorts, as the yellow and moss roses, will not bear severe pruning. The climbing roses should have the old wood frequently cut entirely away, leaving only the young and vigorous shoots.

The rose is a gross feeder, and the soil in which it is planted should be made very rich. Before planting, the ground should be deeply and thoroughly prepared and a good deal of old, well-rotted manure dug in. Every year a liberal supply should be forked in, and frequent applications during the summer of soap suds or liquid manure will be found beneficial.—*Country Gentleman*.

### The Dairy.

#### On the Manufacture of Cheddar Cheese.

[In October last there was a magnificent exhibition of dairy produce at Kilmarnock, Scotland. The Highland Society contributed liberally for premiums. One of them was £20 for the best sweet milk cheese, which was carried by Mr. McAdam, who has kindly furnished an outline of the method he follows in its manufacture.—Ed. Transactions of Highland Ag. Soc'y.]

For various reasons I prefer making my cheese according to the Cheddar system. If the system is carried out with care and intelligence, one is almost certain of obtaining a lot more uniform and superior in quality than could possibly be made on the old Dunlop system. The latter is

neither so easy nor so cleanly. In regard to quantity I have found, after weighing the milk with the utmost care for two successive days, and making one-half on the Cheddar mode, and the other half on the Dunlop, that the result is always in favour of the Cheddar.

The difference, however, in the price of the two kinds of cheese is important. In 1859 I sold my whole stock made in that season at £3 12s. 6d. per cwt., or rather over 14s. 6d. a stone of 24 lbs. In 1860 I sold all my cheese made between 23rd March and 22nd of November, at £3 15s., or upwards of 16s. a stone. Last year I sent the whole to an agent in London, and after deducting all charges, had a return of nearly 14s. 6d. a stone.

On the other hand, I have known of no Dunlop cheese sold during the last five years which has realized anything like what I have done.—The difference has been at least 3s. per stone in favour of Cheddar.

I make my cheese once a day. The evening's milk, as soon as it is drawn from the cows, is put into shallow tin boynees to cool. Next morning this is put through a very fine wire sieve into the steeping tub, while the morning's milk is added as carried in from the byre. In May and the four succeeding months the milk put in this manner together in the evening and morning will generally have a temperature of about 80 degrees Fahrenheit. If it is not so high, a little of the evening's milk is warmed in boiling water to raise the whole to the above temperature. After this, the sour whey, annatto, and as much rennet as will coagulate the whole in an hour, are added and well mixed.

I generally put in about four to five quarts of very sour whey to about 140 gallons of milk. As soon as the curd is properly formed, I commence to break it with a hand-breaker made of tin and wire, which is somewhat like a riddle, and having a wooden handle about three feet long affixed to the middle. When partially broken, the curd is allowed to subside a little. As much whey is then drawn off and heated as will bring the whole up to a temperature of 80 degrees. After this, breaking is resumed, and the temperature maintained by adding more heated whey.

Nothing further is done for the next hour, but to draw off and heat as much whey as will raise the temperature to 100 degrees. At the end of the hour a portion of the whey is run off, and the curd is afterwards very gently broken with a shovel-breaker.

An assistant now gently pours as much heated whey as will once more raise the temperature to 100 degrees. During the time the whey is pouring, the whole is actively stirred, but afterwards more gently, till the curd has acquired proper firmness. I cannot say how long it may be necessary to stir. If too much acid is present, less time is required, and if too little acid, more is necessary. The time will vary, according to these circumstances, from twenty-five to forty minutes.

When stirring is finished, the curd is left half an hour, and then the whey is all drawn off. One side of the tub is raised a little to allow this to take place more perfectly. The curd is then heaped up to the highest side of the tub, covered with a cloth, and left for half an hour. After this interval it is cut into large slices, turned upside down, covered up, and left for another half hour. Then it is torn into thin strips and spread on a cooler, on which it is allowed to lie for another half hour. After thus being turned upside down, it is left another half hour longer.

The curd is then vatted and put into the press on which 28 lbs are suspended for about twenty minutes. Afterwards it is taken out, milled and salted. Cheshire cheese is used at the rate of 2 lbs. to the cwt. It is salted in the cooler, and if it is above the desired temperature it is allowed to lie, perhaps for half an hour, and stirred up once or twice. Our dairy being very warm. I am unable to cool down the curd as low as I could wish before making it up.

On referring to my diary, I find that not one cheeses I exhibited at Kilmarnock was below 68 lbs. when vatted. The cheese is made up between two and three o'clock, p. m., and a dry cloth put on it the same evening. What I make on Monday is carried to the cheese-room on Thursday. Each cheese only gets one dry cloth daily. The room is over the dwelling and dairy. Its temperature during the summer ranges between 65 degrees to 80 degrees. The specimens of cheese I exhibited at Kilmarnock was not subjected to any artificial heat.

I use an oak steeping tub in preference to any other. All the implements and utensils are kept as sweet and clean as possible. The weight or pressure put upon the cheese is the same throughout the different stages of the manufacture.

## The Apiary.

### Fumigating Comb in Bee-Hives,—Moth Traps.

EDS. RURAL NEW-YORKER:—In the impression of the *Rural* dated Nov. 16, 1861, I observed that a correspondent makes the following inquiry:—"Will a sulphur match burned under a hive kill the moth-worm, after removing the bees to another box or hive?"

Yes; the fumes of a burned 'sulphur match, if sufficient, will certainly destroy the moth-worm. Such combs only, however, should be fumigated as are freed from brood, as the fumes of sulphur would be likely to destroy it also. There is but a brief period when all the combs in a hive may be fumigated, without endangering the loss of any brood; the bees of course, should always be first removed, when in a common box-hive, to another box or hive. The period referred to is late in the fall and during the first part of winter. In Western New York,

breeding of bees ceases, in general, about the middle of November, and is again resumed about the middle of January ensuing. It will therefore be observed that there is a recess of about *sixty* days only, during the year, when a good healthy colony has no brood. At this period of the year, when there is no brood, there are but few moth-worms; they are most numerous in warm weather. Very likely there would be as many moth-worms as soon as breeding ceases as at any period during the cessation of breeding. As soon as breeding ceases, therefore, would be the best time to fumigate the combs to insure the destruction of the most worms. In box-hives not supplied with moveable frames, to determine the exact time when there is no brood in the combs, it would be necessary to resort to guessing! I trust that my contemporary is an expert at guessing. To guess correctly is a very essential qualification to such bee-keepers as advocate the old-fashioned box-hive! After having ascertained, by guessing, when the colony has no brood, the bees may be driven out into another box or hive, and the combs thoroughly fumigated. It would be advisable to confine the bees, as they might, having no combs or stores, be tempted to abandon their temporary home. They should be allowed plenty of air. All the crevices about the hive from which the bees were driven should be closed with some suitable material, to confine the fumes of the sulphur as much as possible. Were I to resort to this means of destroying the moth-worm,—but I trust I shall never be obliged to,—I am not positive that I should be content with less than a half-day's fumigation! The moth-worm would never have any desire to get into my hives again! But to return to our subject. After the combs have been thoroughly fumigated, it would be advisable to invert the hive, and subject them for a few hours to the exposure of the air. By this means, a large percentage of the scent of the sulphur will be removed. I should judge that the scent of the sulphur would be quite annoying to the bees: that is, if they were returned immediately after the fumigation, and before the combs had been subject to any exposure to the air. I would here caution the bee-keeper not to use too much sulphur, inasmuch as it be would quite likely to soil the combs; it would color them green.

It will be apparent that the foregoing directions are for fumigating combs in box-hives—hives not provided with frames. Box-hives are the kind that this correspondent, whose inquiry I am answering uses. It is, therefore, not so very strange that he should make the inquiry under consideration. On the other hand, had his bees been in properly made frame hives, and had he learned the fact that the progeny of the bee-moth is an extremely harmless enemy to good healthy colonies of bees, he would certainly

ly not have penned the inquiry which has claimed our attention.

It should be borne in mind by all bee-keepers, that the proper time to destroy moth-worms is early in the spring. They should be destroyed as fast as they make their appearance. At this season of the year every good colony should have more or less brood, which would prevent fumigating the combs with sulphur. We should, therefore, rely upon other means of destroying the worms. It will be obvious that, in case all the worms are destroyed, there would be no millers. The best way that I have found, is to examine my colonies (which, of course, are in frame hives,) quite often in the spring, by taking out the frames of combs, and killing all the worms. When the contents of a hive can be taken out, and each comb can be thoroughly examined on both sides, it must be apparent that it is not difficult to find *every* worm in the hive, and when found, to destroy them. A few worms killed early in spring, are equivalent to a very large number later in the season. Moth-traps are often very useful, and quite as often very injurious. When properly attended to, a great many worms may be caught and killed, but when not properly attended to, they furnish an excellent harbour for the moth-worms, where they often go through the necessary metamorphoses, and at last become millers. The moth worms generally find harboring places enough without providing them with any. It is quite often the case that too much dependence is placed on the moth decoys. The proper place to find the moth-worm is among the combs, and hence the combs should be examined often, and the worms killed before they are old enough to leave them to harbour in the moth decoys; comb being their only food, their ravages are finished when they leave them. All things considered, the *best moth decoys are strong, healthy colonies of bees.* M. M. BALDRIDGE.

Middleport, Niagara Co., N. Y., 1862.

## Veterinary Department.

(Conducted by A. Smith, V. S.)

### Pleuro-Pneumonia.

This disease appears to be still prevailing to a considerable extent amongst the cattle in Massachusetts, and has given rise to some discussion as to its contagiousness or otherwise. The attention of the legislature having been drawn to the existence of the disease in certain districts, a commission has been appointed to enquire into its extent, and adopt measures to arrest its progress. A writer in the *Boston Cultivator* thus narrates the proceedings of the Commission:—

“Immediately upon their appointment, the

Commissioners were notified by the Select-men of Milton, of the existence of the disease in that town in a herd from which two animals had died within a few weeks, and two had been killed by order of the Select-men, being beyond all hope of recovery. The Commissioners entered upon their investigations on the 27th of February, 1862. As investigations progressed, the truth, not only of the existence, but of the contagiousness of the disease, became so apparent, that notwithstanding previous opinions, and the circumstances under which their commissions were granted and accepted, those opinions and prejudices have vanished before the light of truth, and the Commissioners are quietly but faithfully performing the duties of their office, and in my opinion should be spared the odium which some have endeavoured to throw upon a former Board, and should receive the support and co-operation of every friend to the prosperity of the agricultural interest.

I proceed to state briefly, the rise and progress of the disease as developed in this vicinity during the past year, beginning with a pair of oxen sold in Brighton market, in February or March, 1861, one of which was, in the opinion of persons who saw him sick at the time. These oxen were purchased by J. F. Eaton, of Quincy, and taken into his herd. During the next few months not only these oxen, but several animals of his previous herd died; others were sold and taken into other herds, carrying the disease wherever they went; or, if to change the expression will leave the question more open, I will say, the disease *followed* wherever animals from that herd touched. At the present time, the disease has exhibited itself in twenty different herds, and in every instance is traceable to the Eaton herd either directly or through other herds connected with it. I am in possession of the names of the twenty individuals whose herds have been thus affected.

I am of the opinion that the names of some of the parties who have been instrumental in the spread of the disease, might justly be exposed; yet there are others who have ignorantly and innocently contributed in some measure to its diffusion, who have themselves been sufferers, not only in the loss of stock, but in the derangement of their ordinary and legitimate business.

Lest the publication of names should add to the already severe losses of this latter class, I will at present withhold entirely all not already given, holding myself in readiness, not only to give them, but to show, most conclusively, the connection between all of these herds. I deem it proper also to say, that upon different occasions many members of the legislature have witnessed cases of the disease; and I am not aware of an instance where individuals have thus put themselves in the way of ascertaining facts, that they have not only been fully satisfied of the existence of the disease, but also of its contagiousness.

P. STEDMAN.

## Miscellaneous.

**NERVOUSNESS OF PARROTS.**—Parrots are marvellously nervous birds, and, while young, will often throw themselves into such paroxysms of fear at the mere sight of a stranger, that they will even endanger their lives. They have an odd and unpleasant habit of scolding on such occasions, uttering loud, rough, grating cries, as piercing to the ear as the sound of a file or a saw, and stretching out their beaks with ruffled feathers and agitated gestures. Some birds retain this extreme timidity for a very long time, spite of all attempts to conciliate them. I have known a single parrot that was given quite young to a family well skilled in the management of birds, and particularly kind to their feathered pets. Yet, after the lapse of seven or eight months, the bird had only learnt to be tolerably familiar with the feminine portion of the family; and the approach of any man or boy of the same family, or of any stranger whatever, was sure to throw him into a paroxysm of terror.—*Every Boy's Magazine.*

**MINOR EFFECTS IN MONEY SPENDING.**—A correspondent of the *American Agriculturist* writes as follows on a subject of much interest. "There is one thing I would be glad to see more parents understand, namely, that when they spend money judiciously to improve and adorn the house, and the ground around it, they are in effect paying their children a premium to stay at home, as much as possible to enjoy it; but that when they spend money unnecessarily in fine clothing and jewellery for their children, they are paying them a premium to spend their time away from home—that is, in those places where they can attract the most attention, and make the most display."

**RELATIVE VALUE OF FOOD FOR MILK COWS.**—Several French and German chemists estimate the relative value of several descriptions of food for milk cows as follows: That 100lb. of good hay are worth 200lb. of potatoes; 460lb. of beet root with the leaves; 350lb. of Siberian cabbage; 250lb. of beet root, without the leaves; 250lb. of carrots; 80lb. of clover hay, Spanish trefoil, or vetches; 50lb. of oilcake or colza; 250lb. of pea straw and vetches; 300lb. of barley or oat straw; 400lb. of rye or wheat straw; 25lb. of peas, beans or vetch seed; 50lb. of oats; or 500 b. of green trefoil, Spanish trefoil, or vetches.

**YELLOW COLOR IN FLOWERS.**—This is the most predominant color in flowers, and is the most permanent. The yellow of the petals is the only colour which is not discharged by the fumes of sulphuric acid. If, for example, a lighted match is held under them, the purple or any other color will disappear, but the yellow will remain unchanged. Yellow is also a color which, more than any other, baffles the skill of the Photographer.

**ROADS.**—Though advanced as the present age is in civilization and christianity, yet the students of antiquity must acknowledge that we can by no means compete with the ancient Romans in one respect at least, namely, in the construction and stability of our public roads. Nothing can be more conducive to the health of a community than a good dry clean road. Why is it that we have such poor roads throughout the greater part of our State? It is not because we do not spend labor and money upon them. Far from it. But the trouble generally is in our system. We spend a few hundred dollars this fall, and a few hundred next, and so on, yet we always have poor roads. Did we at once lay out a few thousand on them, and, *if possible to find one*, give it to an honest man who would faithfully devote it to the intended purpose, we should soon experience quite a change in the condition of our roads. The following is taken from Dr. Anthon's excellent work on "Roman Antiquities;" it will show what kind of roads they had two thousand years ago:

"The public works were perhaps the greatest of all Roman works, and were constructed with amazing labor and expense. They were generally raised above the ordinary surface of the ground, and frequently had two carriage tracks, separated by a raised foot path in the centre. The centre indeed was always raised, so as to permit the water to run off easily.

"The miles were marked on stones. Stones were also placed at smaller distances for *travelers to rest on*, and to assist those who had alighted in remounting their horses, for stirrups were not used till a late period.

"The military roads were usually laid out in straight lines from one station to another, with little regard to natural obstructions, which were frequently passed by means of very extensive works, as excavations, bridges, and, in some instances, tunnels of considerable length. The solidity of their construction is clearly shown by the existence of many that have borne the travel of near two thousand years without material injury. The Roman engineers were very particular in securing a firm bottom; which was done, when necessary, by ramming the ground with small stones, fragments of brick, &c. On this careful prepared foundation, a pavement of large stones was firmly set in cement. When large blocks could not be conveniently obtained, small ones of hard quality were sometimes cemented together with lime, forming a kind of concrete, of which masses extending to a depth of several feet are still in existence. The most celebrated of the Roman roads, both on account of its length and the difficulties that had to be surmounted in its construction, was the Appian, leading first to Capua, and continued afterwards to Brundisium. It was hence called 'Regina Viarum.' Parts of it still remain, after a duration of more than two thousand years.

UPSILON.

**EXCHANGE OF SEEDS.**—It is a good rule in agriculture, to affect a change of seeds as often as once in every two, or three years. Why it is that the seeds of most of our field crops or grains do better when cultivated on lands at a slight remove from those on which they were matured, is a question which science has as yet been unable satisfactorily to solve; but such is the undeniable fact, and indeed is so obvious, and so clearly corroborated by all experience, as no longer to admit of doubt. The winter and early spring are favorable seasons for exchanging, as well as for procuring new and improved varieties of seeds, plants and scions.

## Editorial Notices, &c.

QUARTERLY AND WESTMINSTER REVIEWS FOR APRIL; AND BLACKWOOD'S MAGAZINE FOR MAY, 1862, American Edition; New York: Leonard Scott, & Co., 70 Eulton Street.

We have received from the publisher, through Mr. Henry Rowsell, of this city, the new numbers of the Quarterly and Westminster; which, as usual, contain valuable articles on the most absorbing topics of the day. These masterly British Periodicals treat with great clearness and ability, all subjects with which all well informed persons must seek to make themselves acquainted. The following articles constitute the numbers before us:—**QUARTERLY:**—Dorset; Hymnology; State and Prosperity of Turkey; Training of the Clergy; Life of Turner; the Eastern Archipelago; Stanhope's Life of Pitt; The Merrimac and the Monitor. **WESTMINSTER:**—The Mythology of Polynesia; Endowed Schools; German Life during the last two centuries; Mrs. Delaney; Caesar's Campaigns in Gaul; The Life of J. M. Turner; The Fathers of Greek Philosophy; Portraits of My Acquaintances; France and Napoleon III.; Lord Stanley; Contemporary Literature. The Contents of BLACKWOOD are as varied and rich as usual. The article on President Andrew Jackson will be read with avidity on this side of the Atlantic.

## BOARD OF AGRICULTURE.

THE Office of the Board of Agriculture has been removed to 188 King Street West, a few doors from the late location adjoining the Government House. Agriculturists and any others who may be so disposed are invited to call and examine the Library, &c., when convenient.

Toronto, 1861.

HUGH C. THOMSON,  
Secretary.

**THOROUGH BRED STOCK FOR SALE.**

**T**HE SUBSCRIBER has for Sale Durham and Galloway Cattle, male and female. Leicester, Cotswold, Lincolnshire, Down and Cheviot Sheep; Cumberland and Yorkshire improved Pigs. All imported stock.

GEORGE MILLER.

Markham, June 3rd, 1862.

6t.

**FOR SALE.**

**A** LOT of thorough bred improved Berkshire Pigs of various ages.

E. L. DENISON,

Dover Court.

Toronto, Aug., 1861.

**Notice of Partnership.**

**T**HE Undersigned have entered into Partnership as Seedsmen and dealers in all kinds of Agricultural and Horticultural Implements, under the firm of James Fleming & Co.

JAMES FLEMING,

GEORGE W. BUCKLAND.

**NOTICE.**

**J**AMES FLEMING & CO., Seedsmen to the Agricultural Association of Upper Canada will carry on the above business, wholesale and Retail, at 126 Yonge-st., 4 doors North of Adelaide-street, until next July, when they will remove to the new Agricultural Hall, at the corner of Queen and Yonge-streets.

JAMES FLEMING will continue the business of Retail Seedsman and Florist at his old stand, 350 Yonge-street.

Toronto, January 1st, 1861.

April, 1862.

**GEORGE LESLIE,  
NURSERYMAN.**

**O**FFERS FOR SALE, THIS SPRING, A GENERAL assortment of Nursery Stock, consisting of

|                              |     |
|------------------------------|-----|
| Apples, Standard and Dwarfs, |     |
| Cherries, do.                | do. |
| Pears, do.                   | do. |
| Plums, do.                   | do. |
| Peaches, do.                 | do. |
| Appricots and Nectarines,    |     |

**GRAPE VINES,**

NATIVE AND FOREIGN.

CURRENTS, GOOSEBERRIES, RASPBERRIES, BLACKBERRIES, STRAWBERRIES, &c., &c.

The collection of fruits cultivated is extensive, and embraces all the different varieties that have been found of value, as well as those of late introduction.

The ornamental department is also extensive, consisting of Shade Trees, Shrubs, Roses, Hardy Herbaceous Plants, &c., &c., with a fine collection of Evergreens.

**LARGE TREES**

FOR

**STREET PLANTING,**

can be supplied, as also Evergreens, and Deciduous Plants for Hedges.

All the above are of FIRST QUALITY. Packing for a distance carefully performed by experienced hands.

All orders by post or left at the Nursery, will have prompt attention.

Catalogues forwarded gratis on receipt of one cent. stamps.

Address

JOURNAL AND TRANSACTIONS OF THE BOARD OF AGRICULTURE  
OF UPPER CANADA.

VOL. XIV.

TORONTO, JUNE 16, 1862.

No. 12.

**The International Exhibition.**

33 CLAPHAM RISE, S.,  
LONDON, ENGLAND, }

*Editor of the Canadian Agriculturist.*

Since I wrote last I have been incessantly engaged in the examination of the various agricultural products of the British Colonies. We have no conception of the variety and value, and the amount of the productions of the Australian colonies until we see them. The progress they have made since 1851 is very remarkable. Queensland is exceedingly well represented. Ceylon, New South Wales, New Zealand, Victoria, and indeed, all those antipodean lands to which emigration has of late been directed, abound in the necessities of life, as well as the staples of manufactures. Specimens of wools of the finest quality, cotton, silk and other fibrous substances, the most valuable minerals, as also some of the best woods for ornamental purposes that can be any where found, are here on exhibition from those colonies. But no colony can compare with our own for the timbers that are useful for general purposes; nor is there a better collection of minerals from any one country than ours. We shall stand high in these two departments, and we will carry off several medals in the classes of Agricultural products.

The jury of which I am a member were yesterday all day in the French department and will be again to day. The exhibition of French agricultural products is very extensive, and the admirable way in which the articles are displayed does the exhibitors very great credit. Large collections have been made from the schools of Agriculture in the various sections of France.—The different cereals are displayed in the straw in a very tasteful manner, and all the varieties

of grains and seeds in glass vessels of various patterns. The whole display is exceedingly interesting, and embraces some two thousand collections by as many exhibitors. You may therefore judge of the amount of labour to be performed, and the difficulty experienced by the jurors in making their awards. Yet we hope that the work will be done and the awards made with a tolerable degree of satisfaction to all parties concerned.

The exhibition has now assumed, with a few exceptions, a finished appearance. Some few things are still being imported, but the confusion incident to the putting up has nearly disappeared. The display of splendid and valuable articles, worth untold millions of money, is now truly astonishing to the visitor.

The cloths from the Netherlands have particularly attracted my attention. They are of the finest quality, and manufactured from the finest wool that is produced in the world, and the prices marked upon them seem to be low enough to induce merchants from the various countries who need such goods to become purchasers.—A vast extension of commercial intercourse must result from this exhibition, while the inhabitants of the various parts of the world who are here assembled will obtain a knowledge of each other which will be by no means the least important benefit that will result from this great collection of men and things.

A contemplation of the whole leads to constant expressions of regret by numerous persons that that wise and good prince who was the originator of the first, should not have been spared to witness the success of this second International Exhibition. But such has been the will of The Great Disposer of the events of the world!

Yours, &c.,

E. W. THOMSON.

## Tanner's Bark as a Manure.

To the Editor of the Agriculturist.

SIR.—The pages of your Journal being ever open to give and receive all information pertaining to the advancement of Agriculture in this fine province, induces me to ask the opinion of the Agriculturist upon the following question:—Having an opportunity of procuring a large quantity of waste tanner's bark, which is the best way to convert it into an active manure? By answering the above in your next impression, you will confer a favor upon

Yours, &c.,  
M. D.  
St. Foy Road, County }  
Quebec, May 24th, 1862. }

### REMARKS.

*Tanner's Bark* occupies a very low position as a fertilizer. Having, however, once been the seat of life, and, therefore, organic, the ingredients of which it is composed, after the tanning principle has been extracted, must, when decomposed, possess in some degree a fertilising power. Something of course will depend on the varieties of wood that have been employed. The bark of the oak and other deciduous trees being preferable to that of the Fir tribe. It is difficult to bring tanner's waste into a rapid state of decomposition, and consequently undesirable to apply it to the land in a crude state. The most preferable mode of employing it is in compost, in connection with light earth and quick lime; the latter when thoroughly mixed in a liberal proportion to the whole bulk, say a tenth or fifteenth, will probably hasten decomposition, and bring the several ingredients of which the bark is made up into a state, in connection with water, for entering into the circulation of plants. Solid liquid manures may be and advantageously mixed with spent bark in a compost; but the use of lime is of the greatest advantage, in promoting the decay of woody fibre, and forms in itself a very valuable auxiliary to a manuring compost. We therefore recommend our correspondent to use the bark at his command in the manner above described; allowing it plenty of time, and thoroughly mixing it together. In this way he may obtain a manure of moderate power, and make it profitable, provided the distance of transportation be not too great.

For the information of our respected correspondent and readers generally, we append an

analysis of Tanner's Bark made, we believe, with great care and accuracy a few years since by Mr. Lonck, of England.

| Tanner's Bark.           | In state in which it was analysed. | Dried at 212° Fah. |
|--------------------------|------------------------------------|--------------------|
| Water.....               | 44.61                              |                    |
| Organic Matters.....     | 48.91                              | 68.58              |
| Inorganic Matters, (Ash) | 6.48                               | 31.42              |
|                          | 100.00                             | 100.00             |
| Containing Nitrogen..    | .069                               | .097               |
| Equal to Ammonia....     | .084                               | .118               |

In 100 parts of the inorganic portion (Ash) of this refuse, were found:—

|                                                                               |         |
|-------------------------------------------------------------------------------|---------|
| Salica and sand.....                                                          | 6.070   |
| Phosphates of lime, magnesia, and iron, containing 1.81 of phosphoric acid... | 5.230   |
| Carbonate of lime.....                                                        | 85.380  |
| Suphate of lime.....                                                          | 1.909   |
| Magnesia.....                                                                 | .215    |
| Potash.....                                                                   | 1.230   |
| Soda.....                                                                     | traces. |
|                                                                               | 100.034 |

It will be observed from the above analysis that spent bark contains a large amount of water, which alone is a sufficient cause to prevent its being applied at any great distance from the locality where it is obtained. Fresh from the yards, it probably is still more completely saturated with water than the specimen analysed.—As might have been expected, nearly all the nitrogenised compounds in the bark have been dissolved during the maceration in water, and only traces of nitrogenised matters are thus left in the organic portion of this waste; for which reason the value of this portion of tanner's bark is but trifling. Moreover, the composition of the ash shows that it principally consists of carbonate of lime and silica, substances of common occurrence, especially the latter, and therefore of little consequence; and that the amount of phosphoric acid and of potash, two valuable fertilising materials is, but very small.

Yet it has been well observed: "Tanner's waste may be used to advantage as a component part of compost heaps; or, partially dried by exposure to the air, it may be economically employed in some places as an absorber for liquid manure, or also for covering manure heaps, to prevent the loss of ammonia in them. Sufficiently dry, it may indeed be used with equal advantage for all purposes for which peat-mould is employed."

## Turnip Culture.

*Editor of the Agriculturist,*

As the benefits which are derived from the growth of this important crop become more widely known, it is yearly receiving a larger space in our fields, a space, yet, however, very diminutive indeed. To cultivate turnips successfully a good deal of labour and attention is indispensable, and perhaps, were we possessed of a practical knowledge of their culture, or proper mode of treatment suited to the requirements of our climate, we should not so often have occasion to complain of a want of success. At your suggestion and request, I shall mention a system which I have found to succeed pretty well; also, a few facts that came under my observation which may possibly be interesting to some of your readers:

In the fall the land intended for turnips was manured with farm-yard manure, and ploughed nine or ten inches deep; cross-ploughed in the spring as soon as it became sufficiently dry, then harrowed and rolled, ploughed again about a week or ten days before sowing, harrowed and rolled until a fine deep tilth was secured. The harrows should be kept going immediately after the plough, or that which is ploughed should be harrowed at least every night, to prevent the moisture from evaporating and the land getting too dry. By thus treating this length of time before sowing, the seeds of weeds are afforded an opportunity to sprout, and are destroyed when drilling commences. There are now many kinds of artificial manures used for turnips, such as guano, bones &c., which are effective in producing large crops, and are much more easily applied than farm-yard manure, on account of their small bulk. Long, poorly rotted manure is ill adapted to this crop, for two reasons: it is not in a fit state to be taken up by the roots of the young plants, at a time they most require to be forced, and it acts injuriously, especially if applied in large quantities in this way; it is with difficulty covered when closing the drills, and when a roller is passed over, a very shallow covering remains in which the seed is deposited; the warm weather and drying winds which we frequently have at this season of the year, dry up the earth on the top of the rough manure, and much of the seed does not sprout at all, and that portion which grows is not unfrequently much injured or quite destroyed before the roots penetrate through the moist earth beneath.

If possible, drills that are opened in the morning should be manured, closed, and sown in the evening. The proper depth to deposit the seed, is a question often discussed. I have these two last years made experiments with reference to this question, and have both times arrived at similar results. The machine with which I sowed would either sow half-an-inch or one-and-a-half deep; that portion which was sown the former depth, braided very irregularly, and

much of the seed never grew at all. That which was sown the latter depth, or one inch and a half, came up much earlier and was altogether a better braird. The only reason I can assign for so marked a difference is that the earth becomes so dry at the former depth—that the seed cannot sprout unless it be favoured with damp or moist weather, when a good braird is secured. The grand secret of success is frequent stirring with the cultivator, or as often as the land becomes hard or baked, taking the weeds in time and keeping them down.

J. W.

June, 1862.

[As our young friend has made so good a commencement, we shall hope to hear from him occasionally, giving the results of his observations and practice. Short practical articles, embodying the results of experience such as many of our readers could, with a little pains, communicate, are what we particularly need.

### Report of the Minister of Agriculture for the year 1861.

*To His Excellency the Right Honourable CHARLES STANLEY, Viscount Monck, Baron Monck of Ballytramon, in the County of Wexford, Governor General of British North America, etc., etc., etc.,*

MAY IT PLEASE YOUR EXCELLENCY:

The undersigned, in conformity with the 6th section of 22 Vic., cap 32, has the honour to submit his annual Report, for the information of Her Majesty's Government.

#### IMMIGRATION.

The encouragement of Immigration forms a most important branch of the duties of the Minister, and is one to which the especial and most earnest efforts of the Department have been directed.

Frequent representations have been made of the great difficulties in procuring accurate information and statistics relating to Canada, experienced by intending emigrants, many more of whom would probably make Canada their home, were her vast resources and the advantages and inducements which she holds out, more widely advertised and proclaimed.

With a view of testing this question, and of enabling Canada to compete more favourably with other British Colonies and the United States, for the advantages attendant upon the settlement of certain classes of emigrants among us, additional agents have been temporarily appointed to represent the emigration branch of this department in the north and south of Ireland and western Europe, respectively.

Mr. Donaldson resumes his old appointment at Londonderry as agent for the north of Ireland; Mr. E. J. Charleton has been appointed to the southern and eastern portion of that country, and Mr. A. H. Verret to western Europe.

With a desire to facilitate the discharge and enlarge the sphere of duties of the Emigrant Office of Lower Canada at Quebec, Mr. Drolet and Mr. Stafford have been nominated Assistant Emigrant Agents for Lower Canada.

Great care has been taken to impress upon the emigrant agents abroad, the importance of their mission, and the fact, that certain classes only of Emigrants are sought for, or desired by the Province. The following extract from the "Letter of Instructions," issued to them by the Minister of Agriculture, relates to this subject:

"In conveying information respecting this country, you will of course readily understand the necessity of great caution and entire truthfulness in any statement you make, in order that the Government may not be involved by representations in any respect fallacious, nor the emigrant, or public abroad be in any way misled. In addition to the authorised documents which you take with you, you will be supplied from this Department with such information bearing on the subject of your mission as you may, from time to time, apply for, or as it may be considered desirable to send you. These communications and your experience and long acquaintance with this country will enable you, at all times, to give such information as shall be really accurate, respecting our mines, forests, fisheries, agriculture, and the Colony generally.

"You will constantly bear in mind that a promiscuous immigration is neither desirable nor sought for: Canada, at present, does not, and for the coming year most probably, will not offer any large field for unskilled labor, since there are no large public works, nor railway extensions in progress. At the same time skilled agricultural labourers can always find ready employment, and female domestic servants are always sure of good wages and certain employment.

"The class of people to whom, especially, Canada offers a desirable home comprises those who on their arrival here are prepared to enter on the Public Lands as settlers.

"The Provincial Government, as you are aware, has recently opened new roads in Upper Canada and in Lower Canada, and has laid out for settlement and authorised free grants (not exceeding 100 acres in each case) of the lands through which these roads pass. These free grants are, however, more advantageous to those acquainted with the climate and country than to the poorest class of emigrants, and those just arrived in the country.

"You will ascertain at the Crown Lands Office the exact position of these free grants now available, and explain fully to persons seeking information the advantages and disadvantages attendant upon their settlement."

The exertions of Emigrant Agents must not, however, be confined to the vast fields of Europe, but it is advisable that they should also be directed to different localities in the United States where former inhabitants of Canada may be found in small communities. Preliminary action has already been taken in this matter by circulating amongst them, in their own language, accurate information as to the advantages which Canada offers to the industry, labour, perseverance, of the Colonists.

The task of collecting and disseminating information likely to be of use to intending emigrants, has been vigorously pursued by the Department. The circular to the Reeves of the townships of Upper Canada and to the Municipal authorities in the Lower Province, making enquiries relative to the number and classes of emigrants sought for in each different locality, and seeking information as to the prices at which "cleared" farms can be purchased or rented, &c., has been re-issued, and the result, compiled and published in a tabular form, circulated largely for the information of emigrants.

In addition to the above, another circular, enclosing a series of questions relative to the quantity and quality of land for sale, statistics and prospects of the settlers, how many are emigrants, &c., nationality, whether any improved farms are for sale or to be let, demand for labour, and general suggestions, has been issued by this Department to the various Crown Land Agents throughout the Province.—The information contained in the answers received to these questions has been condensed and embodied in a pamphlet issued from the Emigration Office by Mr. Buchanan, and extensively circulated in the English, French and German languages.

#### COLONIZATION ROADS.
